System level strategic planning Technology development and demonstration

Informs effective decision making
Underpins national energy systems policy
Develops capacity, technology and engineering
Increases investor confidence

Making energy policy work for the UK

Capacity

Skills, training, infrastructure, science, R+D

Energy

power, heat, transport, infrastructure

Wealth creation

gross value added, direct employment, secondary jobs and impacts, exports, inward investment

What might the UK energy system look like in 2050

- Decided by global developments not just UK events, decisions and policy
 - UK and global economy
 - Industry and technology developments
 - UK demand changes scale and segmentation
 - Global socio-political events
 - International market confidence
 - **–**
- The future is uncertain and we need an energy system design that allows for this

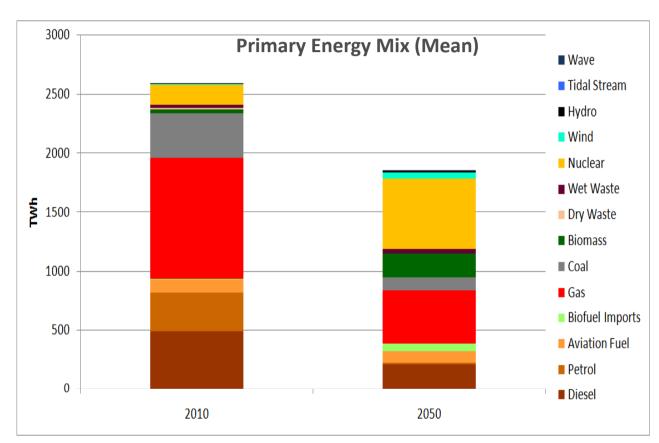

A national energy system design tool Integrating power, heat, transport and infrastructure searching for the lowest cost solution

Getting to 2050

UK primary energy diversifies Nuclear and gas are pillars - 50% of energy imported

- Increasing role for nuclear and renewables
- Fossil fuel persists with CCS in power and as gas in heavy vehicles
- Biomass, onshore wind, hydro and imported biofuels become fully exploited
- Wet wastes must be used effectively – includes conversion to biogas
- Increased range and number of key assets

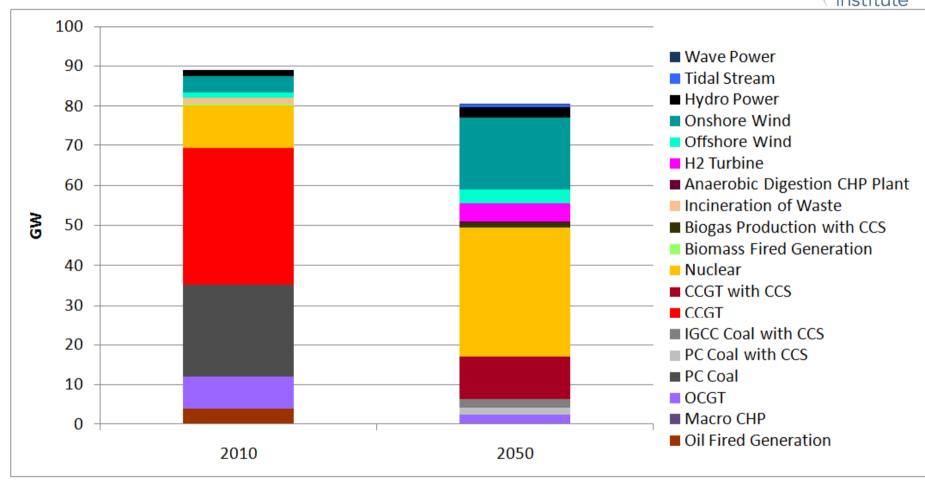

Electricity 2010 = 365TWh, 2050 = 440TWh

UK 2050 power generating capacity

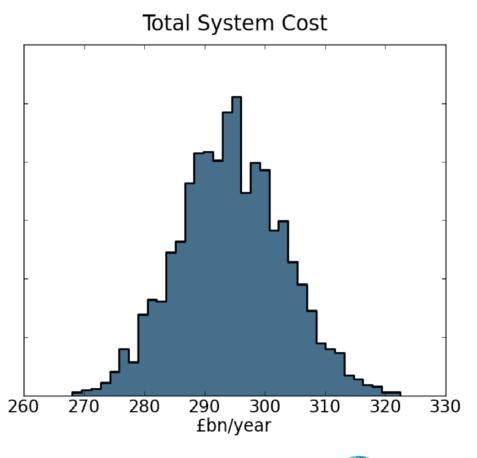

2050 abatement cost is <1% GDP

Biomass and CCS are key levers, nuclear is part of the 'base platform'

| £2010(Mean)/year | | |
|-------------------|------------------|--|
| Total system cost | £294bn | |
| | | |
| Abatement cost | £26bn (0.7% GDP) | |
| Average cost | £51/tCO2 | |
| Marginal cost | £360/tCO2 | |
| | | |
| No biomass | +£44bn | |
| No CCS | +£42bn | |
| No nuclear | +£4bn | |
| | | |
| No tech devt* | +£106bn | |

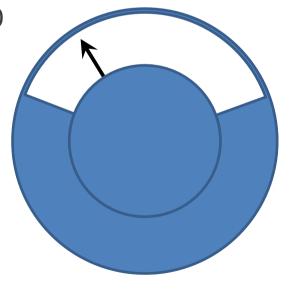

^{*}Assumes current technology cost/performance

Effective national policy needs to focus on things which will 'move the dial'

- Focus on the 'big levers' is crucial to maximise impact of scare resources - money, skills, supplybase and time
- Investment in innovation is critical to reduce costs
- Engagement of industry and consumers is essential
- ETI view immediate development priorities for 2050 as ...
 - Efficiency (technology, consumer demand, storage)
 - Nuclear
 - CCS
 - Bioenergy
 - Offshore wind
 - Gas for transport

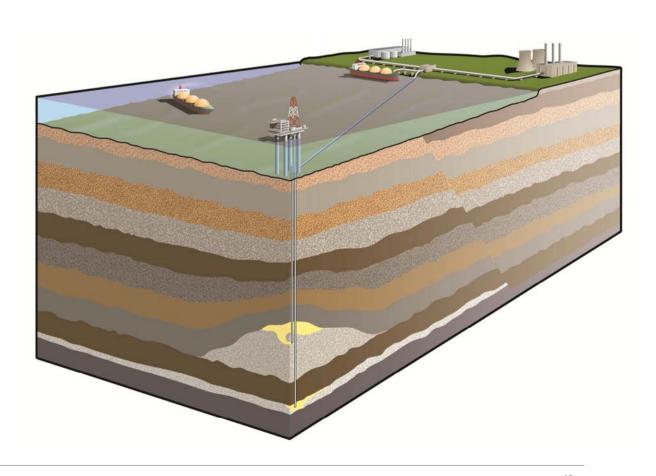

CCS

A key lever - particularly combined with bioenergy Long development time requires early start

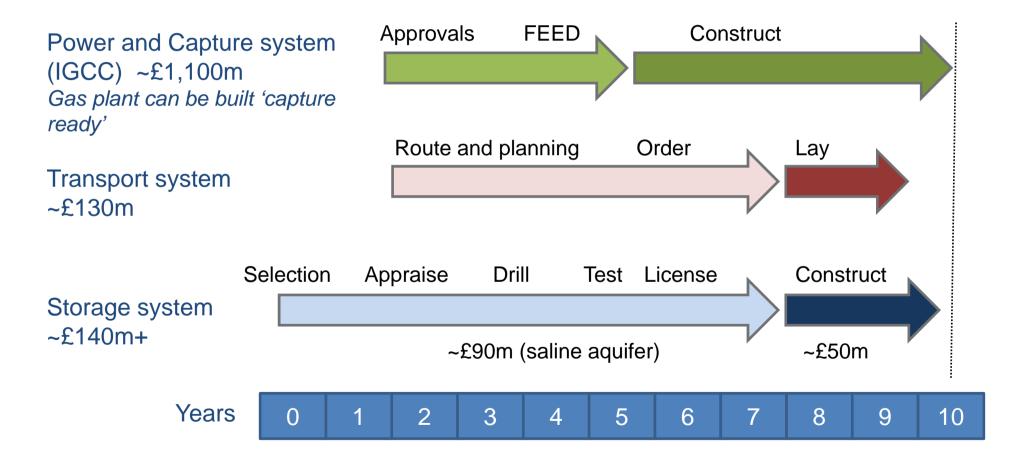

- Potentially very wide use
 - Power
 - Hydrogen and 'Synthetic Natural Gas' (SNG) production
 - Heavy industry
- ETI investing over £60m in enabling CCS for coal, gas and biomass
 - Improved separation technologies
 - Storage appraisal
 - Transport system design tools

Early demonstration start is essential

Longest lead time item is the most uncertain - storage

UK CO₂ Storage Appraisal Project

- Realistic, defensible & fully auditable assessment of potential CO2 storage capacity in the UK
- Unique & comprehensive GIS storage database
 - Capacity
 - Security of storage
 - Economics
 - Underlying data
- Overall estimate of capacity informing CCS investment decisions

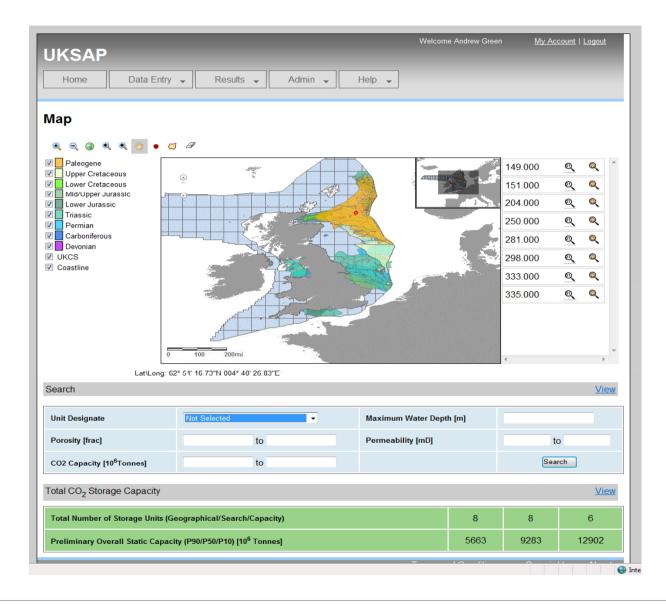

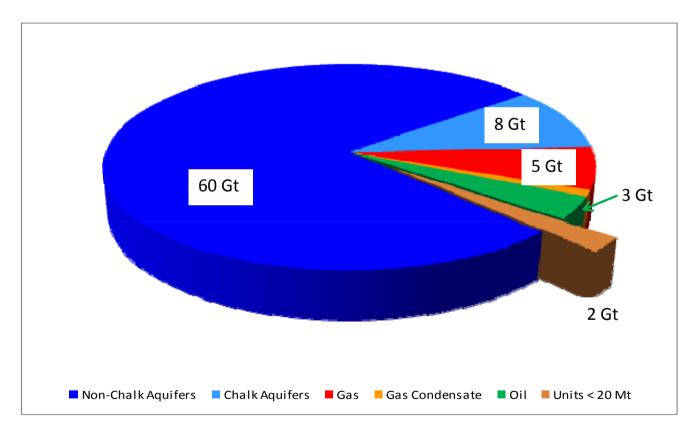

UKSAP Web-enabled Database and GIS

Overall UK CO₂ Storage Capacity

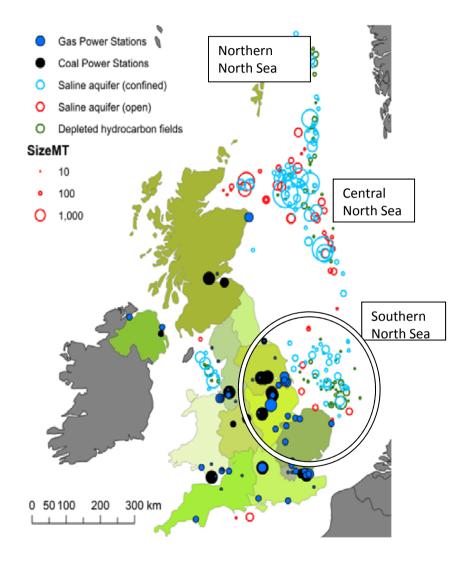

- dominated by saline aquifer stores
- P50 capacity 78GT
- UK requires about 15GT for 100years

- Total 'technical' capacity
 - does not take
 economics and
 security of
 storage into
 account
- Large number
 of stores
 whose final
 assessed
 capacity is less
 than 20 Mt

Where is the storage?

- Viable storage found in all areas studied
- Storage is stacked and clustered – both oil & gas and aquifer
- Opportunities for 'basin scale' approaches

Kev:

Black = coal-fired station Royal blue = gas-fired station Green = hydrocarbon unit Light Blue = closed aquifer Red = open aquifer

Security of Storage

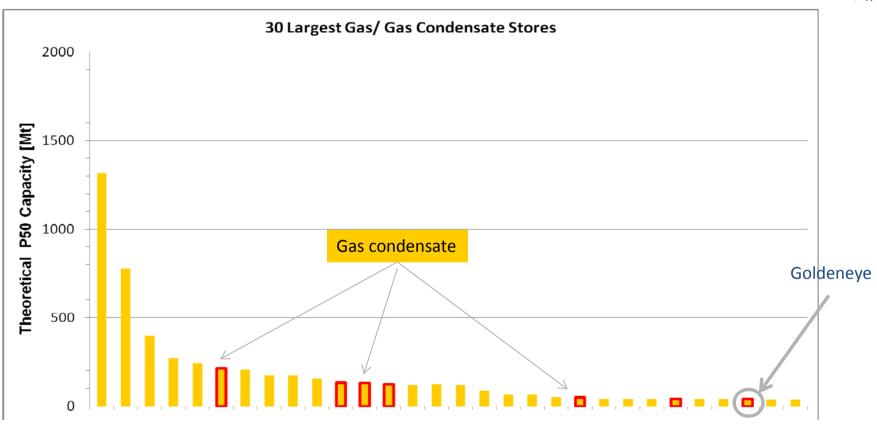

| Formation mineralogy | Seal chemical reactivity Well vintage Formation mechanical integrity Formation salinity | Well density |
|--|--|--|
| Migration dip direction Seal fracture pressure column Migration national boundary Fault compartment. Diagenesis compartment. | Migration depositional trend Migration structural trend Migration rugosity Migration hydrodynamics Strat compartment. horizontal Strat compartment. vertical | Migration dip mag Migration pressure sinks |
| Seal lateral degradation Fault vertical extent | Fault density Fault throw | |
| Low | Medium | High |
| | Migration dip direction Seal fracture pressure column Migration national boundary Fault compartment. Diagenesis compartment. Seal lateral degradation Fault vertical extent | Migration dip direction Seal fracture pressure column Migration national boundary Fault compartment. Diagenesis compartment. Seal lateral degradation Fault vertical extent Migration depositional trend Migration structural trend Migration rugosity Migration hydrodynamics Strat compartment. horizontal Strat compartment. vertical |

- Security of Storage assessments carried out for all saline aquifer units
 - Consistent methodology
 - 23 risk factors considered

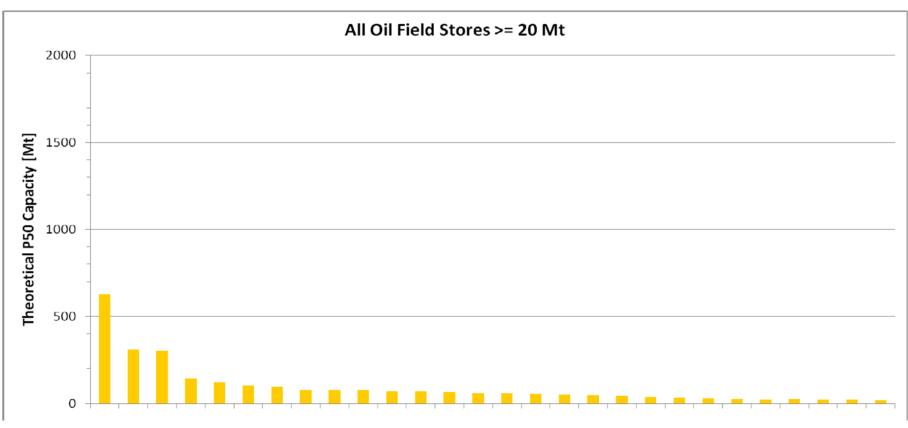

How much storage do we have?

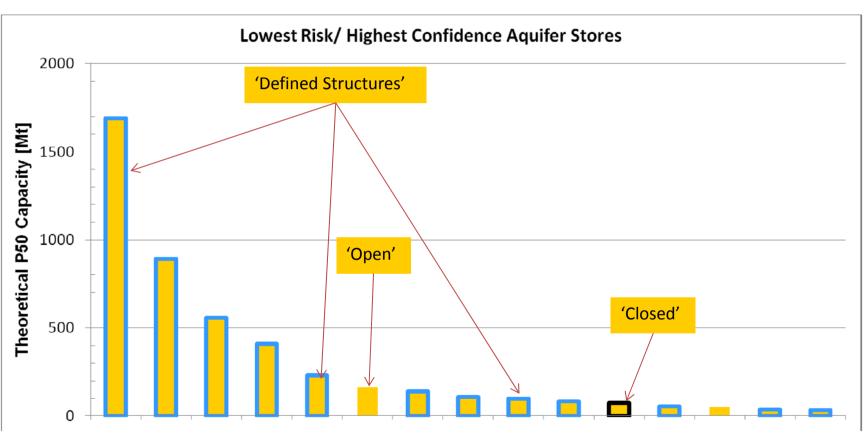

How much storage do we have?

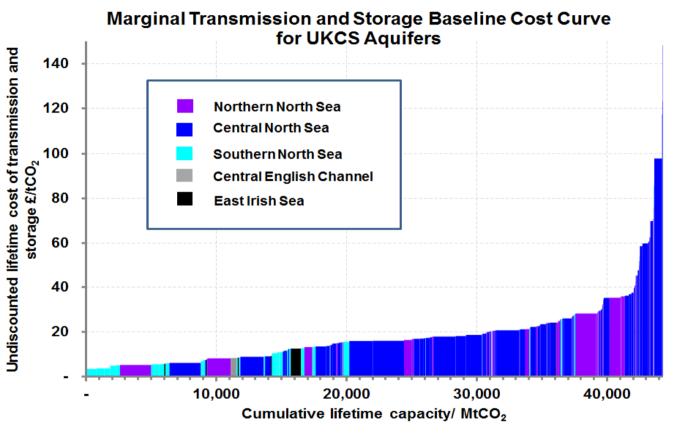

How much storage do we have?

Economics - Aquifers

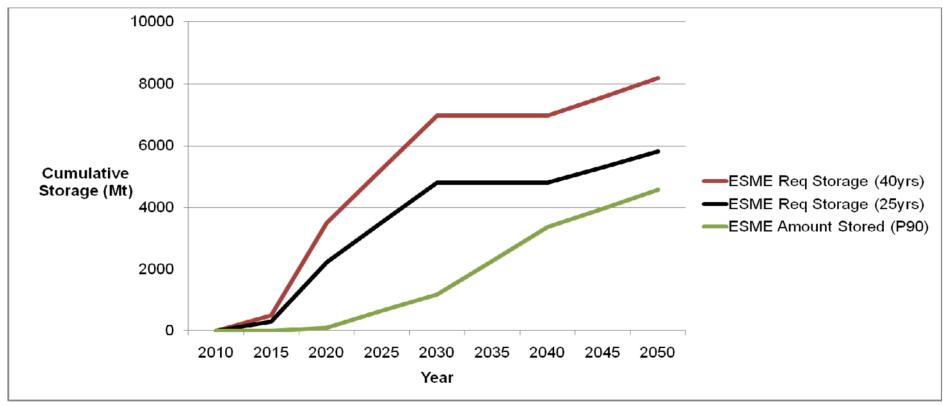

Notes:

- Cost model takes into account key capital and operating costs
- Costs are undiscounted: higher (initial) risk sites will require larger returns on capital
- Transport costs are offshore only, and are based on (shoreline) 'point to point' for each unit

Storage capacity

- must be committed in advance of need

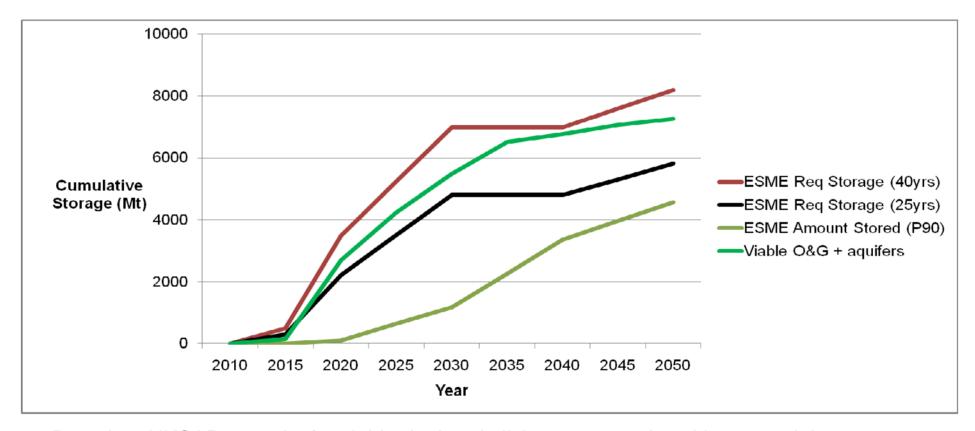

- Assumptions:
 - ESME decadal pathway analysis to 2050
 - Storage Requirement = actual to date + 25/40 years for new assets
- Total UK Storage Requirement (100 years) ~ 15,000 Mt (P90)

2050 pathway requires saline aquifers

- "viable" oil and gas unlikely to meet availability needs for capacity or timing

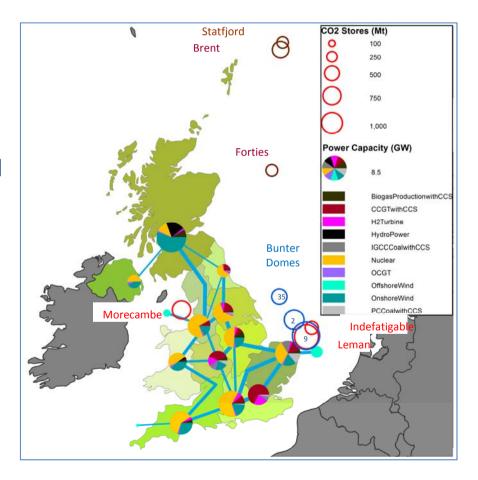

- Based on UKSAP capacity for viable depleted oil & gas reservoirs with 5 year delay
- Availability based on DECC data for Close of Production (smoothed)
- Additional 1,500 Mt appraised aquifer storage available by 2020 rising to 2,700 Mt by 2050

CCS

A key lever - particularly combined with bioenergy Long development time requires early start on storage

- Potentially very wide use
 - Power
 - Hydrogen and 'Synthetic Natural Gas' (SNG) production
 - Heavy industry
- Demonstration projects need to de-risk full value-chain operation and prepare strategic aquifer storage
- ETI investing over £60m in enabling CCS
- ETI UKSAP commercial licensing access currently being finalised
- Strategic management of UK storage required to allow cost effective development and maximisation of resource potential

Delivering low carbon energy technologies Supporting economic growth

by... Informing policy
Building partnerships
Delivering innovation
Sharing risk
Creating affordability
