STARS

• What is a star
• We are formed from the ashes of the stars
• How are stars made?
• How were the first stars made?
THE HOLY GRAIL OF STAR FORMATION

- Can we predict the masses of stars?  □ No
- Can we account for the efficiency of star formation?  □ No
- Can we account for the rate of star formation?  □ No

What’s missing?

A robust theory of star formation

We can still understand the key concepts
if the matter was evenly disposed throughout an infinite space, it could never convene into one mass; but some of it would convene into one mass and some into another, so as to make an infinite number of great masses, scattered at great distances from one to another throughout all that infinite space. And thus might the sun and fixed stars be formed, supposing the matter were of a lucid nature.

if the sun at rest were an opaque body like the planets or the planets lucid bodies like the sun, how he alone should be changed into a shining body whilst all they continue opaque, or all they be changed into opaque ones whilst he remains unchanged, I do not think explicable by mere natural causes, but am forced to ascribe it to the counsel and contrivance of a voluntary Agent.

Isaac Newton, letter to Richard Bentley, December 10, 1692
James Jeans (1877-1946)
James Jeans:

"We have found that as Newton first conjectured....
All celestial bodies originate by a process of fragmentation of nebulae out of chaos, of stars out of nebulae, of planets out of stars and satellites out of planets."

“From the intrinsic evidence of his creation, the Great Architect of the Universe now begins to appear as a pure mathematician.”

Criterion for gravitational stability found by Jeans (1902):

pressure opposes collapse:

sound waves must cross region to communicate pressure changes before collapse
Eddington believed that the number of protons in the universe could be derived exactly:

or

$136 \times 2^{256}$
Arthur Eddington: imagine a physicist calculating on a cloud-bound planet and ending with the dramatic conclusion, "What 'happens' is the stars."

“We can imagine a physicist on a cloud-bound planet who has never heard tell of the stars calculating the ratio of radiation pressure to gas pressure for a series of globes of gas of various sizes, starting, say, with a globe of mass 10 gm., then 100 gm., 1000 gm., and so on, so that his nth globe contains $10^n$ gm. . . . Regarded as a tussle between matter and aether (gas pressure and radiation pressure) the contest is overwhelmingly one-sided except between Nos. 33-35, where we may expect something interesting to happen.

What ‘happens’ is the stars.

We draw aside the veil of cloud beneath which our physicist has been working and let him look up at the sky. There he will find a thousand million globes of gas nearly all of mass between his 33rd and 35th globes – that is to say, between $\frac{1}{2}$ and 50 times the sun’s mass.”

Sir Arthur S. Eddington: The Internal Constitution of the Stars, 1926
What determines the mass of a star?

A struggle between gravity versus (electromagnetic) pressure

It all reduces to one number:

\[ g \frac{G m_p^2 e^2}{2} \approx 3.10^{-37} \]

A dimensionless constant that controls the masses of stars

Its so small because gravity is really weak…while charge neutrality mostly cancels out since electrons are – charged and protons are + charged but it adds up over many atoms, about $10^{57}$ in the sun

There are 3 important stellar masses

mass of the most massive star….the Eddington mass about 100 $M_{\text{sun}}$

mass of the smallest star that burns hydrogen…0.08 $M_{\text{sun}}$

maximum mass of a white dwarf star…the Chandrasekhar mass 1.7 $M_{\text{sun}}$

G is Newton’s constant, $m_p$ is the mass of a proton, $m_e$ is the mass of an electron
The lifetime of a star depends mostly on its mass (and composition)

Thermonuclear fuel supply is proportional to hydrogen mass $M$

Luminosity is proportional to mass cubed $M^3$

So lifetime of a star is proportional to $M/M^3$ or $M^{-2}$

The sun will live for ten billion years.....
but a $100M_{\text{sun}}$ star only lives a million years!

$10^6$ years is a mere instant in the lifetime of the Milky Way, so we should see many dying stars!
The sun
The Sun seen from space
The evolution of the world can be compared to a display of fireworks that has just ended: some few red wisps, ashes, and smoke. Standing on a cooled cinder, we see the slow fading of the suns, and we try to recall the vanished brilliance of the origin of the worlds.

Georges Lemaitre 1931
"I think you should be more explicit here in step two."
Fragmentation into stars

- Fundamental theory applied to a diffuse interstellar cloud that is collapsing under self-gravity
- Minimum **fragmentation** mass
  This is a robust but wrong result!

- Resolution: **fragmentation** + continuing **accretion** of cold gas, halted by **feedback** that taps stellar energy via magnetic turbulence

- accretion rate=\((\text{sound speed})^3/G\) and lack of metals means warmer clouds
  **first stars were massive!**

\[ m_p \approx 0.01 M_{\text{sun}} \]

\[ m_p \approx \frac{3}{2} \alpha \frac{1}{G} \]

\[ m_p \approx \frac{2}{e^2} \]

\( m_p \) is the mass of a proton

\( \alpha \) is the fine-structure constant =1/137
Magnetic fields are everywhere in the universe. They control the rate at which stars form today.
Dust is everywhere in the universe
Numerical simulation of first star formation

- Just gas cooling by hydrogen molecules
- No dust
The first stars: fragmentation

The Formation of Population III Binaries from Cosmological Initial Conditions
Turk, Abel, & O'Shea 2009
How to find traces of the first stars

• First stars were massive and short-lived
• But their enriched debris polluted interstellar clouds
• The next generation of stars included many less massive survivors
The first stars are very metal poor

The third most iron-poor star in the Galaxy

a fossil from the first star population

Christlieb et al. (2004)
STELLAR BIRTH
STELLAR YOUTH
30 Doradus in the Large Magellanic Cloud
STELLAR MATURITY
Many stars are not alone
STELLAR DEATH
A massive star evolves hydrogen, helium, carbon, nitrogen, oxygen, iron, and explodes. From its ashes, our solar system formed.
supernova remnant
Star deaths create the chemistry of the universe

Mass distribution of newly born stars
I. Bonnell
Have we directly detected POPULATION III?

POP I is the MW disk: young stars

POP II is the MW halo: old stars

POP III is the hypothetical population of the first stars

Milky Way look-alikes
Have we detected the real POPULATION III?

- POP I is the MW disk
- POP II is the MW halo
- POP III is the population of the first stars

- The only example so far is at redshift 6.6: CR7
  strong in hydrogen and helium emission, no metals

Sobral 2015
The first stars

- They are massive & long gone but their polluted environment survives
- Interstellar clouds contaminated by metals form long-lived low mass stars
- We recognise these as being the lowest metallicity stars in our galaxy
- Their abundance patterns trace the masses of the first stars: they are fossils
- We may be already seeing them far far away
