

INACTIVE SEWAGE SYSTEMS

Systems are designed only to store wastewater, which the tank and trucked off-site for treatment. If systems cannot be accommodated, these depend on an alarm to warn when nearly full, or going contract with a pumping service.

Alternatives to septic systems are available on active systems, using compressors or air into the treatment of wastewater. Most ble air through wastewater, or use rotating swage to air.

Contrast, a septic system, unless it uses a pump to discharge to the leaching bed, has no moving parts and requires no electricity.

Robic systems can provide a higher level of treatment than standard septic tanks. They also require lubrication, electrical connections and more frequent maintenance than conventional systems.

The local Health Departments have been reluctant to approve these designs, because of problems that have arisen from improperly installed systems; the same size drainage field may be required for an aerating system as for a standard septic system.

New Technology

These systems are improving as new technologies are further developed and demonstrated. Research into improved mechanical systems, better biological treatment media and systems using wetland or aquatic plants appears very promising. The University of Waterloo's Centre for Environmental Research is one of the leaders in
