

## Reading Sample

This chapter describes the displayable elements of HTML that you can use between <body> and </body>. It discusses how to create a single web page using HTML and mark it up with the appropriate elements. Topics covered include splitting an HTML document into separate and meaningful section, using headings in a predetermined order, implementing a header and footer, splitting and grouping text content, tagging semantic elements, and using and displaying unordered and ordered lists.

## Chapter 4 <br> The Visible Part of an HTML Document

This chapter describes the displayable elements of HTML that you can use between＜body＞and＜／body＞．For designing or laying out websites， you should use CSS instead．Before you learn how to make a website more beautiful，you need to have the basic knowledge of how to create a single web page using HTML and mark it up with the appropriate elements．

Even if you＇ve already created web pages in HTML 4.01 （or even earlier）and are already familiar with the handling of HTML elements，it＇s worth working through this chapter because semantic elements have been added with the current HTML and many exist－ ing elements have been given a different semantic meaning．

Here＇s what you＇ll learn in this chapter：
－Splitting an HTML document into separate and meaningful sections with new HTML elements such as 〈section＞，〈article＞，〈aside＞，or 〈nav＞
－Using headings in a certain order and implementing a header and／or footer with the new＜header＞and＜footer＞elements
－Splitting and grouping text content with HTML elements
－Semantic tagging of text such as single letters，words，or parts of sentences with HTML elements
－Using and displaying unordered and ordered lists via＜ul＞and＜01＞

## 4．1 HTML Elements for Structuring Pages

In this chapter，you＇ll learn about the various HTML elements that you can use to divide a web page into useful sections．If you＇ve used HTML 4.01 so far，you＇ll find many new elements here，as the current HTML also introduces a new content model to combat the rampant use of div elements with class attributes．

| HTML Element | Meaning |
| :--- | :--- |
| ＜body＞ | Displayable content section of the HTML document |
| ＜section＞ | Subdivision of the HTML document into different sections |

Table 4．1 Quick Overview of the Section Elements Covered Here

| HTML Element | Meaning |
| :--- | :--- |
| <article> | Subdivision of content into a self-contained topic-specific block |
| <aside> | Marginal information of a content such as a sidebar or for additional <br> information about an article |
| <nav> | Element used to mark up navigation(s) such as a sitemap or the main <br> navigation of the website |
| <h1>, <h2>, <h3>, <br> <h4>, <h5>, <h6> | Headings of the first through sixth order |
| <header> | Header of a content |
| <footer> | Footer of a content |
| <address> | Contact information for the author of the content |

Table 4.1 Quick Overview of the Section Elements Covered Here (Cont.)

### 4.1.1 Using <body>: The Displayable Content Section of an HTML Document

Everything you write between the opening <body> tag and the closing </body> tag is referred to as the HTML document body. Between <body> and </body>, you can write all HTML elements, such as text, hypertext links, images, tables, and lists, to define the structure of the web page. All elements written between <body> and </body> are rendered by the web browser and displayed accordingly.
<!doctype html>

<html lang="en">
<head>
<title>Title of the document</title>
<meta charset="UTF-8">
</head>
<body>
This is the content of the document, which is to be
rendered and displayed by the web browser
</body>
</html>

### 4.1.2 Introducing the Section Elements of HTML

The following sections introduce the section elements of HTML, that is, <section>, <article>, <aside>, and <nav>. If you're perhaps just getting into HTML, using section elements is still a bit confusing or disappointing at first because they change almost
nothing visually. Primarily, these elements only serve to divide the content into semantic (i.e., meaningful) areas.

Even if these new elements don't seem to make sense to you yet, just remember that they aren't of interest to the normal user of the website, but are mainly used to give meaning to the content, which is particularly useful for the developer, the search engines, and the screen readers.

## Dividing Content into Topic-Based Sections Using 〈section>

The <section> element allows you to divide the content of a document into topic-based sections. This is helpful, for example, if you want to divide a document into individual chapters or even subchapters-just like this book was divided into individual sections. Even on an ordinary homepage, you can use this element to create individual content and sense sections, such as a section with the description about the owner of the website, another section with news, and one with contact information. Here's a simple example, the result of which you can see in Figure 4.1:
...

<body>
<section>
<h1>Chapter 1</h1>
<p>The first chapter</p>
</section>
<section>
<h1>Chapter 2</h1>
<p>The second chapter</p>
<section>
<h2>Chapter 2.1</h2>
<p>A subchapter of Ch. 2</p>

\section*{</section>}

\section*{</section>}
</body>
- 

Listing 4.1 /examples/chapter004/4_1_3/index.html

In this example, the <section> element has been used to divide the document into meaningful sections-in this case, Chapter 1 and Chapter 2-with each chapter consisting of a heading <h1> and paragraph text <p>. Furthermore, it's possible to nest <section> elements, as shown within the <section> element of Chapter 2, Section 2.1.

Figure 4．1 Between＜section＞and＜／section＞，You Can Divide the Content of a Document into Meaningful and Logical Units

## Dividing Content into a Self－Contained Block Using 〈article＞

You should use the article element to summarize a piece of content in a self－contained topic－specific block．The article element is in itself quite similar to the＜section＞ele－ ment，which you use to divide the content into meaningful sections．However，it＇s rec－ ommended that you use the article element for a standalone composition，which would be ideal for individual news items，blog or forum entries，or comments on a blog post or news，for example．
Here＇s an example of an HTML code snippet that shows you what such a blog entry with the article element could look like．The result is shown in Figure 4．2．
．．．
＜body＞
＜h1＞My Blog＜／h1＞

＜／footer＞
＜／article＞
＜／body＞
．．
Listing 4.2 ／examples／chapter004／4＿1＿4／index．html

## My Blog <br> article $705.6 \times 134.31$ L

## New HTML elements on the horizon

Published on 2023－05－05
As already suspected

Figure 4．2 The Example Shows a Meaningful and Logical＜article＞Composition of a Blog Entry

Everything between＜article＞and＜／article＞is the composition of a self－contained block consisting of a heading，a timestamp，the actual content section，and a footer．It＇s up to you to decide which HTML elements you want to use to create such a composi－ tion with＜article〉，but the example shown here already makes sense semantically．

## What to Use：＜article＞or＜section＞？

You＇re probably wondering which of the two elements you should use for a semantic separation of content because the two are somewhat similar in some respects．Never－ theless，the HTML specification also makes a differentiation here and recommends using＜article＞if certain semantics are to be used multiple times，as is the case with a news or blog entry．Thus，＜article＞is a self－contained block－a composition of repeat－ edly used content following the same pattern－whereas＜section＞is suitable for a separation into content sections，which should contribute to a better overview of the entire document．

## Adding Content with Additional Information Using 〈aside＞

With＜aside＞，you can usually supplement or expand content with additional informa－ tion．Strictly speaking，you can use the aside element for two different semantic things： a sidebar or an additional piece of information（e．g．，a citation）to a content item，for example，within an article element

Referring to the／examples／chapterOO4／4＿1＿4／index．html example from the previous section，for example，you would use＜aside＞for a separate logical section in the docu－ ment：
＜body＞
＜h1＞My Blog＜／h1＞
<p>Latest reports on HTML</p>

<article>
...
</article>
<aside>
<h3>Partner websites</h3>
<ul>
<li><a href="\#">Blog XY</a></li>
<li><a href="\#">Magazine X</a></li>
<li><a href="\#">Website Z</a></li>
</ul>
</aside>
</body>
...

aside $705.6 \times 95.51$
Partner websites

- Blog XY
- Magazine $X$
- Website Z

Figure 4.3 The <aside> Element Is Used as a Separate Logical Section in the HTML Document

$$
\begin{aligned}
& \text { Note } \\
& \text { The \# character in HTML is a reference to a jump mark in the same document, but it has } \\
& \text { no meaning yet in this example and was used instead of a real destination address. }
\end{aligned}
$$

In addition to the option just shown, using <aside> as a sidebar would also be suitable as additional information in the form of a quote or within an article element. In the example that contains the blog entry, it would be suitable within the article element for an entry with further links to the blog entry.

\section*{Declaring Content as a Page Navigation Bar Using <nav>}

As you might guess from its name, the nav element enables you to divide navigation elements into blocks. We're not talking about web link collections here, but about a list of links for a sitemap or the main navigation of your own website. Like the aside element, you can use the nav element for its own section or within another HTML element to combine a group of links into a block.
To use the blog entry again as an example, the nav element would be suitable for summarizing the main navigation or the list of related links from similar articles within the same web page. In any case, you should use the nav element for entire blocks of links. The following code snippet demonstrates the nav element in a small theoretical blog:
\[
\ldots
\]
<body>
<nav>
<a href="\#">Blog</a> |
<a href="\#">Links</a> |
<a href="\#">About me</a> |
<a href="\#">Legal Notes</a>

Figure 4.5 The <nav> Element (Colored Here) Can Be Used to Divide a Separate (Navigation) Section or to Group Blocks of Links within Other HTML Elements

In the first example, <nav> was used to define a main navigation as a separate section of the HTML document. In the second example, the nav element was used to link a block of links to similar articles on the same web page. In the last example, a sitemap of the web page was summarized via the nav element.
In addition, the last two examples were grouped within <aside> and </aside>. In them, bulleted lists (ul and li elements) were used within the nav element.

> Using <nav> Only for Main Navigation?
> The specification suggests using the nav element specifically for the main navigation. That doesn't include external additional links or affiliate links to external websites. Likewise, it's not recommended to put legal stuff such as copyright, contact information, and legal notes in the nav section; instead, use the footer section for that purpose (see Section 4.1.4).
> In the /examples/chapter004/4_1_6/index.html example, this means you only have two main navigation points with Blog and Links within the nav element and would write About me and Legal Notes outside of it (e.g., in the footer). I don't see any point in separating this because there's no difference between the first two links (Blog and Links) and the other two links (About me and Legal Notes) as both are linked to different websites, and both belong to the internal website in this case. So, it's up to you to what extent you want to follow these recommendations. In any case, you should refrain from using the nav element for external links to third-party websites and, if possible, use it only selectively and sensibly on your own website.

\subsection*{4.1.3 Using Headings with the HTML Elements from <h1> to <h6>}

The HTML element for headings of a certain order is \(\langle h 1\rangle\) to \(\langle h 6\rangle\). The number (1 to 6) represents the heading level. Thus, everything you write between <h1> and </h1> is used as a top-level heading, everything between <h2> and </h2> belongs to a secondlevel heading, and so on down to the lowest level with <h6> and </h6> as a sixth-level heading.
The HTML elements <h1> through <h6> should not be misused to emphasize a text, but rather to define the content structure of a document. Consider the following HTML structure:
<h1>Heading 1</h1>
<h2>Heading 1.1</h2>
<h3>Heading 1.1.1</h3>
<h2>Heading 1.2</h2>
<h2>Heading 1.3</h2>
<h3>Heading 1.3.1</h3>

\section*{<h1>Heading 2</h1>}

Based on this sequence of headings, the following content structure (or document outline) will be mapped:
1. Heading 1
1.1. Heading 1.1
1.1.1. Heading 1.1.1
1.2. Heading 1.2
1.3. Heading 1.3
1.3.1. Heading 1.3.1
2. Heading 2

\section*{Heading 1}

Heading 1.1
Heading 1.1.1
Heading 1.2
Heading 1.3
Heading 1.3.1

\section*{Heading 2}

Figure 4.6 This Is What the Web Browser Will Make of It

\section*{What Happens to the Headings in the Section Elements?}

You're probably wondering what happens to the content structure of headings when you use the section elements from Section 4.1.2. That question is well justified. If you use the <section>, <article>, <aside>, or <nav> section elements, the content structure of the headings will also be affected. Within each new section element, the heading level count starts from the beginning, but always at a lower hierarchy level. The following HTML code illustrates this:
..
<body>
<h1>My Blog</h1>
<p>A simple blog ...</p>
<section>
```
    <h1>News on HTML</h1>
    <article>
    <h1>A preview of the new HTML elements</h1>
    <p>It looks like ...</p>
    </article>
</section>
<section>
    <h1>News on CSS</h1>
    <article>
        <h1>New Styles at Last</h1>
        <p>After a long time of development ...</p>
    </article>
<section>
</body>
```

Listing 4.6 /examples/chapter004/4_1_7/index.html

Here，five＜h1＞headings of the first order were used．If you look at the HTML code，you can see several sections．Next to the top section with＜body＞，you can find two addi－ tional＜section＞elements，each of which contains an＜article＞element in which head－ ings of the first order have also been defined．
This is a blog that＇s been divided into two content sections with＜section＞containing the topics HTML and CSS．Within these sections，you can find the news articles included within 〈article＞．

\section*{My Blog \\ A simple blog ．．． \\ News on HTML \\ A preview of the new HTML elements \\ It looks like ．．． \\ News on CSS \\ New Styles at Last \\ After a long time of development ．．．}

Figure 4．7 All Headings with＜h1＞Are Adjusted and Output Corresponds to the Section due to the Section Elements of HTML That Are Based on the Outline Algorithm

Due to the use of the new HTML elements＜article＞and＜section＞，the following con－ tent structure（or document outline）results：

1．My Blog
1．News on HTML
1．A preview of the new HTML elements
2．News on CSS
1．New Styles at Last

\section*{Document Outline for Advanced Users}

The term outline or document outline refers to the structure of the document，which can be generated and represented by the headings，among other things－as in the case of the table of contents of this book，for example．The document outline can be quite useful．For example，the web browser might offer you a table of contents，letting you jump from one heading to another．Search engines can also use such a table of contents to create better page previews or even improve search results．Screen reader users probably have the biggest advantage here because they can be guided through deeply nested hierarchies and sections．
In Figure 4．8，you can see the JavaScript HTML5 outliner（h5o）to test the document out－ line during execution．Here，the document outline is displayed in the upper－right cor－ ner，and you can jump to the individual headings via hypertext links．

\section*{My Blog \\ A simple blog ．．．}
```

\section*{News on HTML}

\section*{A preview of the new HTML elements}

It looks like ．．．

\section*{News on CSS}

\section*{New Styles at Last}

After a long time of development ．．．
Figure 4．8 JavaScript h5o from Google during Execution

Section elements such as 〈section＞，＜article＞，〈aside＞，and＜nav＞allow you to refine the document outline even more，as you＇ve seen in the example，／examples／chap－ ter004／4＿1＿7／index．html．

Even if not all web browsers support document outlines directly，it won＇t do any harm to pay attention to a proper outline of the HTML document because basically that＇s no extra work．Screen reader users will thank you for it，and search engine robots may reward you for it because a good document outline can improve a page index，which in turn could mean a higher ranking in search results．Besides，a neatly structured web page is easier to read than an unstructured one．

\section*{Keeping Track of the Document Outline}

When the website becomes more extensive and the document contains many head－ ings and perhaps different sections，it often isn＇t easy to keep track of whether the doc－ ument outline still makes sense and is neatly structured with regard to its contents． Outlining tools that output the headline structure of the web page in the existing struc－ ture can assist you here．For example，Google offers the JavaScript h5o，mentioned in the previous section，at https：／／h5o．github．io．Alternatively，you can find an online service at http：／／gsnedders．html5．org／outliner／．Meanwhile，the validation checker at https：／／validator．w3．org／nu／\＃textarea also provides an outline option for HTML docu－ ments．

\section*{4．1．4 Creating a Header Using＜header＞and a Footer Using＜footer＞}

The＜header＞and＜footer＞are two additional semantic HTML elements that you can use for implementing a header and footer in an HTML document．Like section ele－ ments，these elements initially have no visual effect on the HTML document apart from a line break．Again，these are initially just elements that you can use to give a piece of content a better and cleaner structure．The styling here is usually done via CSS．How－ ever，unlike section elements such as 〈section＞，〈article＞，〈aside＞，or＜nav＞，these two elements don＇t affect the hierarchical structuring（or document outline）of the docu－ ment．

You should use the header element for introductory elements such as a page heading， the name of the web page，or a navigation bar of the HTML document．There may well be other HTML elements between＜header＞and＜／header＞．However，you mustn＇t nest any other header elements in it．Although it seems obvious，＜header＞doesn＇t necessar－ ily have to be in the header，and you can use it more than once in the document．
```
Invalid Positions of <header>
A＜header＞tag mustn＇t be used inside a footer，address，or another header element．
```

The counterpart to the header element for the header section is the footer element for the footer or also the footer section，which also doesn＇t necessarily have to be the last element in the document．Useful content for the footer of a website is often legal
information，legal notes，or terms and conditions，but you can also use a sitemap or a special navigation bar here．You can＇t use any other＜footer＞tag within a footer

Here＇s an example that demonstrates the header and footer elements in a meaningful structure：
．．．
＜body＞
＜header＞

```

Figure 4．9 The Header and Footer with the＜header＞and＜footer＞Elements（Shown in Gray for Clarity）

Between <header> and </header>, you can find a summary of the entire information for the header section of a web page. In the example, this is the version of the blog, the headline, and a short description of the website. This is followed by the articles of the blog. Finally, the footer between <footer> and </footer> contains forwarding hyperlinks with legal information and so on.

\subsection*{4.1.5 Marking Contact Information Using <address>}

You should use the address element only for contact information about the author of the HTML document or article. If the address element is used within the body element, it should only contain the contact information for the owner or author of the entire document or article. If the address element is positioned inside an article element, the contact information for the author of the document should be written there. Usually, the web browser displays this text in italics with a new line before and after the address element.

The best location for this contact information for the author, an organization, or the person responsible for the document or article is usually likely to be at the end of the article or at the end of the document (e.g., between <footer> and </footer>).
Here's an example in which the address element was used for contact information about the author of an article at the end inside the footer element. You can see the example at execution in Figure 4.10.

\subsection*{4.2 HTML Elements for Structuring Text}

This section describes the HTML elements for grouping or structuring plain text content, such as paragraph text or a line break. This has nothing to do with dividing an HTML document into individual sections or areas. You've previously learned how to do that in Section 4.1.
\begin{tabular}{|l|l|}
\hline HTML Element & Meaning \\
\hline <p> & Text paragraph \\
\hline <br> & Forcing a line break \\
\hline <wbr> & Optional line break within a word \\
\hline <hr> & Topic-based separation at the paragraph level \\
\hline <blockquote> & Citation as a text paragraph \\
\hline <div> & Defining a general section \\
\hline <main> & Used for the main content area of a web page \\
\hline <figure> & Grouping or summarizing content for separate description \\
\hline <figcaption> & Labeling content grouped via the figure element \\
\hline <ul> & Unordered bulleted list \\
\hline <ol> & Ordered list (mostly numbered) \\
\hline
\end{tabular}

Table 4.2 Brief Overview of the Elements Covered Here for Grouping and Dividing Content
\begin{tabular}{|l|l|}
\hline HTML Element & Meaning \\
\hline <li> & List element in a ul or ol list \\
\hline <dl> & Creating a description list using dt and dd \\
\hline <dt> & Expression to be described before the dd element \\
\hline <dd> & Description that follows the dt element \\
\hline
\end{tabular}

Table 4.2 Brief Overview of the Elements Covered Here for Grouping and Dividing Content (Cont.)

\subsection*{4.2.1 Adding Text Paragraphs Using <p>}

The \(p\) element ( \(p=\) paragraph) is the classic element for text paragraphs in a longer continuous text. Anything you write here between the opening <p> and the closing </p> is treated as a text paragraph. Within such a text paragraph you can use images, videos, audio clips, or other text markup in addition to multiline body text. However, you can't use other group elements, headings(<h1> to <h6>), or section elements within <p> and </p>.
The following example demonstrates two slightly longer paragraph texts with the \(p\) element in use:
<body>

Figure 4.11 Two Paragraphs with Body Text between < p > and </p> Displayed in the Web Browser

\section*{Aligning and Formatting Paragraph Text Using CSS \\ Paragraph text with the \(p\) element can be formatted using CSS or CSS features}

\subsection*{4.2.2 Forcing Line Breaks Using <br>}

If you try to insert a line break or a space in the body text of the example just shown, /examples/chapter004/4_2_1/index.html, you'll notice that it doesn't work. The point at which the line break is supposed to be inserted is decided by the web browser based on a space that separates words. Nevertheless, you can also force a line break at a certain point in the text using <br> (br = break). <br> is a standalone tag. Even though you can use multiple line breaks simultaneously via <br>, you shouldn't overuse it for separating paragraphs.
The following example is commonly used to represent an address neatly by means of forced line breaks (see Figure 4.12):
... Written by <a href="mailto:\#">John</a><br>
<address>
John Doe<br>
Sample Town<br>
www.address.com
</address>
...
Listing 4.10 /examples/chapter004/4_2_2/index.html
```
Written by Joh
John Doe
Sample Tow
www.address.com
Legal | Legal Notes | T&Cs | About me
```

Figure 4.12 You Can Force Line Breaks via the <br> Element

\subsection*{4.2.3 Adding Optional Line Breaks Using <wbr>}

If, on the other hand, you need an optional line break that only occurs at a specific position when it's necessary for an optimal display in the web browser and to save the user from scrolling sideways, you can use the standalone <wbr> (or <wbr /> in XHTML) tag for this (wbr = word break). <wbr> can be quite useful if you want to prevent the web browser from breaking a line in the wrong place. A simple example follows:
<p>Taumatawhakatangi<wbr>
hangakoauauotamatea<wbr>
turipukakapikimaungah<wbr>
oronukupokaiwhen<wbr>
uakitanatahu</p>
Depending on how wide the display section is in the web browser, the long word can be wrapped only at the places where <wbr> was inserted.
```
Taumatawhakatangihangakoauauotamateaturipukakapikimaungah
oronukupokaiwhenuakitanatahu
Legal | Legal Notes }|\underline{T&Cs}|\underline{\mathrm{ About me}
```

Figure 4.13 An Extremely Long Word Wrapped at a Position Suggested by <wbr>

\section*{Line Break via <wbr>}

The optional line break via <wbr> was added to the standard HTML version at a later time, but it had been around since HTML 2.0. The Netscape web browser had introduced this element a long time ago, and other browser manufacturers had implemented it as well.

Nevertheless, this word separation is unattractive because the line gets broken without consideration of a grammatically correct separation. As an alternative, the named entity \&shy; is suitable for a conditional hyphen. Similar to <wbr>, this allows the web browser to separate the word at this point if necessary. Unlike <wbr>, the web browser adds a hyphen at the end of the wrapped word. The alternative example looks as follows:
<p>Taumatawhakatangi\&shy
hangakoauauotamatea\&shy;
turipukakapikimaungah\&shy;
oronukupokaiwhen\&shy;
uakitanatahu</p>

Taumatawhakatangihangakoauauotamateaturipukakapikimaungahoronukupokaiwhenuakitanatahu

\section*{Legal \(\mid\) Legal Notes \(\mid\) T\&Cs \(\mid\) About me}

Figure 4.14 A Long Word Can Also Be Wrapped at the Position Suggested by "\&shy;" but It Also Adds a Separator, Unlike <wbr>

\subsection*{4.2.4 Forcing Spaces and Preventing Wrapping Using "\&nbsp;"}

If you want to insert multiple spaces between two words, you can force this with the named character \&nbsp; (\&nbsp = nonbreaking space). Let's take a look at a simple example:
<p>word1\&nbsp;\&nbsp;\&nbsp;\&nbsp;word2</p>
<p>word3 word4</p>
Between word1 and word2, the named HTML entity character \&nbsp; has been written four times, resulting in four spaces between these two words, which is also displayed by the web browser. In the example with word3 and word4 the same was tried by pressing the spacebar four times. Nevertheless, in this case, the web browser displays only one space between the words.

In addition to forcing a space, you can also use the named entity character \&nbsp; to prevent a break between two words, which the web browser automatically performs when there is insufficient space at the end of a line. For example:
... word1\&nbsp;word2 ...
By placing this \&nbsp; between word1 and word2, you can prevent the two words from being split between two different lines by the web browser if there's a lack of space word1 and word2 thus stick together in the same line forever.

\subsection*{4.2.5 Adding a Topic-Based Separation Using <hr>}

You can use <hr> to create a topic-based separation in an HTML document, for example, to separate content more clearly. However, even though <hr> is visualized as a separator in HTML by web browsers, the element is also to be treated as a semantic element and not a presentation element. For example, it isn't valid HTML to use the hr element between <p> and </p> or within a heading (<h1> to <h6>), even though web browsers are quite fault-tolerant about this.

The example shown in Figure 4.15 with a horizontal line can be found under/examples/ chapter004/4_2_5/index.html. You'll see that a separator line also creates a paragraph.

\subsection*{4.2.6 Adding Paragraphs or Citations Using <blockquote>}

Between <blockquote> and </blockquote>, you can quote a text from another source. Most web browsers indent the text in a new paragraph. Within such block quotes, you can use other HTML elements besides text.

The blockquote element contains cite, an HTML attribute that allows you to specify the source of the citation. With regard to books, this can also be a link to the corresponding book page or to a store where this book can be purchased. Unfortunately, no web browser provides the option to somehow make this source visible or to call the corresponding URL yet. So, to be on the safe side, you should add the source, as I did in the following example; in Figure 4.16, you can see the display in the web browser.
<blockquote cite="http://www.blindtextgenerator.com/">
Nulla consequat massa quis enim. Donec pede justo,
fringilla vel, aliquet nec, vulputate eget, arcu. In enim
justo, rhoncus ut, imperdiet a, venenatis vitae, justo.

\subsection*{4.2.7 Defining a General Section Using <div>}

Between <div> and </div> (div = division), you can define a general section, which at first usually does nothing but create a new line. This div element doesn't have any meaning until CSS comes into play, which is the main use of <div>: defining layout sections. In the following example, the HTML attribute class was used, which you can use to assign the div elements to a class that you can later select with CSS (using a selector) and visually customize or style. Here's a familiar example that demonstrates such an application in use:
...
<body>
<div class="header">
<hr />
<h1>My Blog</h1>
<p>A simple blog ...</p>
<hr />
</div>
<h2>News on HTML</h2>
<div class="article">
<h3>A preview of the new HTML elements</h3>
<p>Lorem ipsum dolor ...</p>
</div>
<div class="footer">
<hr />
<a href="\#">Legal</a> |
<a href="\#">Legal Notes</a> |
<a href="\#">T\&Cs</a> |
<a href="\#">About me</a>
<hr />
</div>
</body>
...
Listing 4.12 /examples/chapter004/4_2_7/index.html

For such examples, you should prefer semantic elements such as <header>, <footer>, <article>, <nav>, and so on instead of the div element.

Therefore, you should use the div element only if no other suitable HTML element is available. You can find more information about this in greater detail in Section 4.3. In regard to the /examples/chapter004/4_2_7/index.html example, you should, as previously described in the book, use the HTML elements <header>, <article>, and <footer> that have been newly introduced in HTML instead of the <div class="header">, <div class="article">, and <div class="footer "> sections used in the previous example. The corresponding example thus looks as follows (see Listing 4.13).

### 4.2.8 Using <main>: An HTML Element for the Main Content

I described the div element in the previous section, so it makes sense to deal with the main element at this point. Where <div id="main">...</div> was used in the past, you can use <main>...</main> from now on. The id attribute identifies an element that occurs only once within a document.
Like all other new HTML elements, you should use the main element as sensibly as possible. In practice, you use it for the main content of a website, which means it's best not to place it inside <article>, <aside>, <footer>, <nav>, or header elements.
In the web browser, the main element is rendered like the div element with no special properties and only creates a line break. However, unlike the div element, you should use the main element only once (visibly) in an HTML document. In contrast to the <section> element, the main element isn't a section element, but a pure grouping element. Thus, the use of such a section doesn't affect the heading structure (the document outline) of the HTML document.
Here's an example of how you can group a section as the main section of a web page:
.

$$
\cdots
$$

<body>
<header>
<h1>My Blog</h1>
<p>A simple blog ...</p>
</header>
<main>
<h2>News on HTML</h2>
<article>
<h3>A preview of the new HTML elements</h3>
<p>Lorem ipsum dolor...</p>
</article>
</main>
<footer>
<a href="\#">Legal</a> |
<a href="\#">Legal Notes</a> |
<a href="\#">T\&Cs</a> |
<a href="\#">About me</a>
</footer>
</body>
...
Listing 4.14 /examples/chapter004/4 2 8/index.html

## Using <main> Multiple Times?

<main> is intended to present the main content of an HTML document and should therefore be included only once in a document. If it's used more than once, then this page won't pass the validation check. Nevertheless, there are single-page web applications, that is, applications that consist of a single HTML document and whose content is dynamically reloaded, where this rule can become an issue. For this reason, the use of the main element has been adjusted somewhat, and multiple main elements can now be used. However, only one <main> element of those can be visible at a time. All other main elements must be provided with the hidden attribute. For example
<main>...</main>
<main hidden>...</main>
<main hidden>...</main>
Although there are other ways in CSS to hide individual elements, you can use only the hidden attribute with <main> for the HTML document to be valid. All other options are invalid.

### 4.2.9 Labeling Content Separately Using <figure> and <figcaption>

To set off or group certain content such as tables, images, listings, videos, or other HTML elements from the usual body text, you can use the figure element. If you want to link this section with an (optional) caption, you should use the figcaption element. Like the figure element, the figcaption element can contain other HTML elements besides ordinary body text. Thus, the figure element serves as the semantic parent for an element belonging to the page content, such as an image, table, listing, or other content, and the figcaption element encloses the subtitle to that element.
Here's a simple example, the result of which is shown in Figure 4.18:
...
<h2>HTML</h2>

<article>
<h3>figure and figcaption in use</h3>
<p>The text before figure ...</p>
<figure>
<img src="opera.jpg" alt="Chinese Opera" />
<figcaption>Figure 1: Once upon a time ...</figcaption>
</figure>
<p>The text after figure</p>
</article>
...
Listing 4.15 /examples/chapter004/4 2 9/index.html

If you want to place the (optional) caption with the figcaption element before the content (above the image in the example), you need to use the element right after the opening <figure>. However, it's only possible to use a figcaption element between <figure> and </figure>, and <figcaption> must be the first or last element of the figure element.

## My Blog

A simple blog ...

## HTML

figure and figcaption in use figure $823.2 \times 215.4$

Figure 1 : Once upon a time ..
The text after figure
Legal $\mid$ Legal Notes $\mid$ I\&Cs $\mid$ About me
Figure 4.18 In the <article> Element between <figure> and </figure>, an Image Has Been Inserted with the <img> Element and a Caption with the <figcaption> Element

Between <figure> and </figure> you can also use more than one content type (e.g., an image in the example). In the web browser, a figure usually doesn't get displayed separately. In addition to a separate line, the content between <figure> and </figure> is often displayed slightly indented. However, CSS is used for the design of the figure element anyway.

### 4.2.10 Creating Unordered Lists Using <ul> and 〈li>

An unordered list is basically nothing more than an unnumbered bulleted list in which all list entries are given a bullet character. The web browsers usually display this bullet with a bullet point.

You can introduce such a list with an opening <ul> (ul = unordered list), followed by the actual bullet points, which you write between <li> and </li>. Each li element (li = list item) is a bullet point. At the end, you must end the unordered bullet list with the closing
</ul>. Only li elements can be contained between <ul> and </ul>. In between the li elements, you can also use other HTML elements (except for section elements).

Here's a simple example of an unordered list, the execution of which you can see in Figure 4.19.
...

<article>
<h2>Unordered bullet list with ul</h2>
<ul>
<li>Lorem ipsum dolor sit amet</li>
<li>Donec quam felis ultricies</li>
<li>Nulla consequat massa quis</li>
<li>Etiam ultricies nisi vel</li>
<li>Donec vitae sapien ut libero</li>
</ul>
</article>
...
Listing 4.16 /examples/chapter004/4_2_10_15/index.html

## Unordered list with ul

Lorem ipsum dolor sit amet
Donec quam felis ultricies
Nulla consequat massa quis

- Etiam ultricies nisi vel
- Donec vitae sapien ut libero

Figure 4.19 Bulleted Lists with the <ul> Element Are Usually Displayed with a Bullet Point

### 4.2.11 Creating Ordered Lists Using <ol> and <li>

What you've just read about the ul element also applies to the ol element ( $01=$ ordered list). The only exception is that the ol element is an ordered list-more precisely, a numbered list in which the individual li elements are automatically numbered. Here's an example of an ordered list, the execution of which you can see in Figure 4.20.

<article>
<h2>Numbered bullet list with ol</h2>
<ol>
<li>Lorem ipsum dolor sit amet</li>
<li>Donec quam felis ultricies</li>
<li>Nulla consequat massa quis</li>
<li>Etiam ultricies nisi vel</li>
<li>Donec vitae sapien ut libero</li>
</ol>
</article>
...
Listing 4.17 /examples/chapter004/4_2_10_15/index.html

2. Donec quam felis ultricies
3. Nulla consequat massa quis
4. Etiam ultricies nisi vel
5. Donec vitae sapien ut libero

Figure 4.20 The Numbered List with the <ol> Element Uses Arabic Numerals by Default

### 4.2.12 Reversing the Numbering of an Ordered List

With HTML, it's also possible to reverse the order of numbering via the HTML attribute reversed in the opening <ol> tag, so that the numbering gets displayed in descending order. Based on the preceding example, you only need to insert the following:

<ol reversed="reversed">
|01>

Besides <ol reversed="reversed">, you can also just use <ol reversed> here because it’s a standalone attribute. But if you want to be XHTML compliant, you must use the form <ol reversed="reversed">. In HTML, you can use both versions.

\section*{Numbered list with ol (reversed)}
5. Lorem ipsum dolor sit amet
4. Donec quam felis ultricies

Nulla consequat massa qui
Etiam ultricies nisi vel
1. Donec vitae sapien ut libero

Figure 4.21 The Numbering Order Was Reversed via the "reversed" Attribute

\subsection*{4.2.13 Changing the Numbering of an Ordered List}

You can use the HTML attribute start to specify the start value of the first li element in the opening <ol> tag. All values that follow the first li element are incremented by the
value 1. Even within an opening <li> tag, you can use the HTML attribute value to change the numbering of the list entry. All subsequent entries are incremented by the value 1 using the value specified in value.
The execution of the following example is shown in Figure 4.22
...
<ol start="20">
<li>Lorem ipsum dolor sit amet</li>
<li>Donec quam felis ultricies</li>
<li>Nulla consequat massa quis</li>
<li value="101">Etiam ultricies nisi vel</li>
<li>Donec vitae sapien ut libero</li>
</ol>
...

## Change the numbering of an numbered list

20. Lorem ipsum dolor sit amet
21. Donec quam felis ultricie
22. Nulla consequat massa quis
23. Etiam ultricies nisi vel
24. Donec vitae sapien ut libero

Figure 4.22 The Starting Numbering Was Set to 20 Right in the Opening <ol> Tag with the Attribute "start" and Then Again in an Opening <li> Tag with the Attribute "value" to 101

### 4.2.14 Nesting Lists within Each Other

You can nest both numbered lists and bulleted lists. Such nested lists are used when, for example, you need a finer structuring of the lists, such as a table of contents (e.g., at the beginning of this book). A navigation with submenus is also often formulated by means of a bulleted list.

Nesting lists can get a little messy, so if you have a deeper bulleted hierarchy, you should use indentations and/or add a comment. When nesting, the li elements aren't nested inside each other, as might be assumed, but a ul or ol element must be written again with the nested li elements inside an opening parent <li> tag. Only when you close the opening <li> tag with </li> will this list be marked and displayed as a child list.

The execution of the following code snippet is shown in Figure 4.23.
<h2>Nesting bullet lists ul</h2>

<ul>
<li>Lorem ipsum dolor sit amet

\section*{<ul><!-- Start: 1. Nesting -->}
<li>Donec quam felis ultricies</li>
<li>Nulla consequat massa quis</li>
</ul><!-- End: 1. Nesting -->
</li>
<li>Etiam ultricies nisi vel</li>
<li>Donec vitae sapien ut libero</li>

## </ul>

<h2>Nesting numbered lists ol</h2> <ol>
<li>Lorem ipsum dolor sit amet

<ol><!-- Start: 1. Nesting -->
<li>Donec quam felis ultricies</li>
<li>Nulla consequat massa quis</li>
</ol><!-- End: 1. Nesting -->
</li>
<li>Etiam ultricies nisi vel</li>
<li>Donec vitae sapien ut libero</li> </ol>

2. Donec quam felis ultricies
3. Nulla consequat massa quis
4. Etiam ultricies nisi vel
5. Donec vitae sapien ut libero

Figure 4.23 The Nesting of Unnumbered Lists and Numbered Lists during Execution
Of course, you can nest the lists even deeper. Mixing unordered and ordered lists is also possible without any problem. Unfortunately, it isn't possible to force automatic numbering such as $1.2,1.3,1.4$, and so on for the numbered sublists.

To illustrate this, the following is an example of a deeper and mixed nesting, the result of which is shown in Figure 4.24.
...
<h2>Deeper nesting and mixing lists</h2>

<ol>
<li>Lorem ipsum dolor sit amet
<ol><!-- Start: 1. Nesting -->
<li>Donec quam felis ultricies</li>
<li>Nulla consequat massa quis
<ol><!-- Start: 2. Nesting -->

Figure 4.24 Further Nesting Depths and Mixing of Ordered and Unordered Lists

## Omitting the Closing Tag from Lists

As you may remember from Chapter 2，Section 2．1．6，it＇s possible to omit the closing tags in some places．Especially if a list is deeply and extensively nested，this may even be clearer and easier than setting the closing tags．As mentioned earlier，this style isn＇t used in this book，and l＇ve never used it in practice（yet）．Nevertheless，it should be pointed out here because the lists are listed as a pro－argument，especially by the＂omis－ sion faction．＂

## 4．2．15 Creating a Description List Using 〈dl＞，〈dt＞，and＜dd＞

In HTML，there＇s another type of list you can use－the description list．This list is more of a name－value mapping list．Typical use cases for the description list are glossaries or the listing of special metadata and values；in other words，it＇s simply a special list with certain data in which a value or a description is assigned．
A description list gets summarized between＜dl＞and＜／dl＞（dl＝description list）．The dl element may only contain the $d t$ and dd elements described in the same way．The expression to be described，that is，the name of the name－value mapping list，is marked with＜dt＞and＜／dt＞（dt＝description term）．The associated description is written after the $d t$ element between＜dd＞and＜／dd＞（dd＝definition description）．In turn，other HTML elements may be used in dt and dd elements－except for grouping elements and HTML elements for new sections（sectioning）．

Here＇s a simple example of a description list，the result of which is shown in Figure 4．25． By default，web browsers display the descriptions（＜dd＞elements）slightly indented compared to the expression（＜dt＞elements）．Here the description list was used for a list of abbreviations in the web jargon．

．．．
Listing 4.21 ／examples／chapter004／4＿2＿10＿15／index．htm

Figure 4.26 The Description List for an Image (a Book) Has Been Wrapped inside the <details> Element, Allowing the Description to be Expanded and Collapsed

### 4.3 Using Semantic HTML

Now that you know the HTML elements for page structuring and text structuring, you may be wondering how you can create a basic web page with these HTML elements so that it makes sense semantically. Specifically, this means that you can define the different logical parts of a web page with HTML tags. By the way, the semantic web isn't just a fad, but helps search engines, for example, better allocate the sheer flood of data on the internet. Search engines such as Google even prefer semantic web pages and searches HTML pages for semantic content.
Let's take as a simple example the term goal, whose meaning in hockey is different from that in business. The term gets its assignment and meaning only if you provide the relevant context. This is roughly how you can imagine the semantic web: you contextualize the content with code so that machines can also interpret and process it.

### 4.3.1 HTML without a Precise Structure

The first example is a classic HTML document that has no detailed structure: ...
<h1>My Blog</h1>
<p>A blog with yummy recipes ...</p>

```
<p>Navigation:
    <a href="#">Blog</a> | <a href="#">Recipes</a> |
    <a href="#">About me</a> | <a href="#">Legal Notes</a>
</p>
<h2>0ld Posts</h2>
<ul>
    <li><a href="#">Last Week</a></li>
    <li><a href="#">Archive</a></li>
</ul>
<h2>Tasty homemade vanilla sauce</h2>
<p>Today I want to show you how ...</p>
<h3>Similar recipes</h3>
<ul>
    <li><a href="#">Chocolate sauce made from cocoa</a></li>.
    <li><a href="#">Custard Made Easy</a></li>
</ul>
<p>
    <a href="#">Contact</a> | <a href="#">FAQs</a> |
    <a href="#">About me</a> | <a href="#">Legal Notes</a>
</p>
Listing 4.22 /examples/chapter004/4_3_1/index.html
```

There isn't much to note about this example. The HTML code is valid and can be used like that. You can see some headings, unordered lists, navigation, and various paragraph texts. However, such code is rarely used because it's nearly unstructured and is relatively poorly suited for styling or laying out via CSS.

```
My Blog
A blog with yummy recipes.
Navigation: Blog | Recipes | About me | Legal Notes
Old Posts
    - Last Week
Tasty homemade vanilla sauce
Today I want to show you how ...
Similar recipes
    - Chocolate sauce made from cocoa
Contact | EAQs | About me | Legal Notes
```

Figure 4.27 /examples/chapter004/4_3_1/index.html When Displayed in the Web Browser

### 4.3.2 Generic Structuring Using <div>

The first example didn't contain any element to tell you where the different sections of content were located. For this reason, we'll now use the div element to divide the content into separate sections. Take a look at the same example again now, but this time it contains the div elements:

<div>
<h1>My Blog</h1>
<p>A blog with yummy recipes ...</p>
</div>
<div>
<p>Navigation:
<a href="\#">Blog</a> |
<a href="\#">Recipes</a> |
<a href="\#">About me</a> |
<a href="\#">Legal Notes</a>
</p>
</div>
<div>
<h2>0ld Posts</h2>
<ul>
<li><a href="\#">Last Week</a></li>
<li><a href="\#">Archive</a></li>
</ul>
</div>
<div>
<h2>Tasty homemade vanilla sauce</h2>
<p>Today I want to show you ... </p>
<h3>Similar recipes</h3>
<ul>
<li><a href="\#">Chocolate sauce made from cocoa</a></li>.
<li><a href="\#">Custard Made Easy</a></li>
</ul>
</div>
〈div>
<p>
<a href="\#">Contact</a> |
<a href="\#">FAQs</a> |
<a href="\#">About me</a> |
<a href="\#">Legal Notes</a> </p>

## </div>

## Listing 4.23 /examples/chapter004/4_3_2/index.html

This time, the content was separated by means of div elements. Nevertheless, we still don't see any semantic elements. Visually, nothing changes here compared to the /examples/chapter004/4_3_1/index.html example from the previous section.

All that can be achieved by using the div element is to group a piece of content together. Thus, it depends on the author of the web page to assign meaning to the individual div elements. Before semantic elements came into play, this was done via attributes in the opening <div> tag. So, let's now take a look at the next step and the next example, in which the individual div elements get their meaning:

<div id="header">
〈h1>My Blog</h1>
<p>A blog with yummy recipes ...</p>
</div>
<div id="navigation">
<p>Navigation:
<a href="\#">Blog</a> |
<a href="\#">Recipes</a> |
<a href="\#">About me</a> |
<a href="\#">Legal Notes</a>
</p>
</div>
<div id="sidebar">
<h2>Old Posts</h2>
<ul>
<li><a href="\#">Last Week</a></li>
<li><a href="\#">Archive</a></li>
</ul>
</div>
<div id="content">
<h2>Tasty homemade vanilla sauce</h2>
<p>Today I want to show you ...</p>
<h3>Similar recipes</h3>
<ul>
<li><a href="\#">Chocolate sauce made from cocoa</a></li>.
<li><a href="\#">Custard Made Easy</a></li>
</ul>
</div>
<div id="footer">
```
<p>
    <a href="#">Contact</a> |
    <a href="#">FAQs</a> |
    <a href="#">About me</a> |
    <a href="#">Legal Notes</a>
</p>
</div>
```
...

Listing 4.24 /examples/chapter004/4_3_2/index2.html
While nothing has changed in a purely visual sense, the div elements have gained meaning thanks to the id attribute. We now have a header, navigation, sidebar, content, and footer as it's visually represented in Figure 4.28. Using CSS, you can design and lay out these areas individually. This way, you can virtually already achieve a semantically correct structuring of the website, but not yet a semantically unified structuring.

Figure 4.28 The Meaning for the Layout Areas Is Assigned via <div> and the "id" Attribute
So why should you use semantic structuring at all when you can work with div elements without any problem? There are several reasons for this: Despite the use of IDs
in the div element, you have a semantically neutral element. It isn't a standardized structuring, but instead everyone can define what they want. For the machines, there's still no difference here. They can't know what you really mean by id="header" or id= "content" and what's behind it. You might as well write id="head" or id="synopsis" or whatever in all the languages of the world.

For example, imagine a smart screen reader reading the main content of the web page to a visually impaired person. How would the screen reader know what the main content is? One web developer may write id="content", another may write id="main", and you may write id="musings". In addition, some web developers don't mark up the main content at all.

The situation is the same with search engines. For search engines to return a better result, it's helpful if they know what belongs to the main content of the web page. Again, the search engine faces nonstandard class and ID names. Thus, it's an advantage here if you tell the web crawler on the next visit: this is the main content of my site

\section*{<div> Can Still Be Used in HTML}

Using div elements and labeling the layout sections with the ID and class names are by no means incorrect-they represent valid HTML. In addition, the div element often helps you solve a problem. Nevertheless, for future projects, you should use the new semantically meaningful elements that were introduced especially for this purpose.

\subsection*{4.3.3 Semantic Structuring Using the Elements Provided in HTML}

To write a semantically meaningful structure as HTML code for machines, there are suitable elements in HTML that have already been described in the book and are listed once again in Table 4.3.
\begin{tabular}{|l|l|l|}
\hline HTML Element & Meaning & Section in This Chapter \\
\hline header & Header sections & Section 4.1.4 \\
\hline nav & Navigation blocks & \begin{tabular}{l} 
Section 4.1.2 and "Declaring Content as a Page \\
Navigation Bar Using <nav>" on Page 102
\end{tabular} \\
\hline section & \begin{tabular}{l} 
Division into content \\
sections
\end{tabular} & \begin{tabular}{l} 
"Dividing Content into Topic-Based Sections \\
Using <section>" on Page 97
\end{tabular} \\
\hline article & \begin{tabular}{l} 
Division into self- \\
contained blocks
\end{tabular} & \begin{tabular}{l} 
"Dividing Content into a Self-Contained Block \\
Using <article>" on Page 98
\end{tabular} \\
\hline aside & Additional Information & Section 4.1.2 \\
\hline footer & Footer sections & Section 4.1.4 \\
\hline & & \\
\hline
\end{tabular}

Table 4.3 Semantic HTML Elements

Returning to our example /examples/chapterOO4/4_3_2/index2.html, this HTML code should do without div elements and instead rely on semantic HTML elements:

\section*{<header>}
<h1>My Blog</h1>
<p>A blog with yummy recipes ...</p>
</header>
<nav>
<p>Navigation:
<a href="\#">Blog</a>
<a href="\#">Recipes</a> |
<a href="\#">About me</a>
<a href="\#">Legal Notes</a>
</p>
</nav>
〈aside>
<h2>01d Posts</h2>
<ul>
<li><a href="\#">Last Week</a></li>
<li><a href="\#">Archive</a></li>
</ul>
</aside>
<article>
<h2>Tasty homemade vanilla sauce</h2>
<p>Today I want to show you ...</p>
<h3>Similar recipes</h3>
<ul>
<li><a href="\#">Chocolate sauce made from cocoa</a></li>.
<li><a href="\#">Custard Made Easy</a></li>
</ul>
</article>
<footer>
<p>
<a href="\#">Contact</a> |
<a href="\#">FAQs</a>
<a href="\#">About me</a>
<a href="\#">Legal Notes</a>
</p>
</footer>

Listing 4.25 /examples/chapter004/4_3_3/index.html

When you look at the HTML document with the semantic elements, it's probably already much easier to recognize at first glance what has which meaning here. This is just a simple example. Here you can immediately see the header, navigation, sidebar, main content, and footer (see Figure 4.29). This way, the content could perhaps also be placed inside the main element in which the individual articles are then summarized using the article element.

Figure 4.29 Layout Areas Marked with HTML Semantic Elements

The point here isn't at all where you can use exactly which HTML element in detail, but rather that this semantic structuring makes sense, even if you've never heard of new elements such as nav, article, header, footer, and so on. The logic here is almost selfevident. It's much easier to see where the navigation, header, or footer is written in this document.

\footnotetext{
The Main Content with <main>
If you still want to summarize the main content of the web page in <main> in the exam ple /examples/chapter004/4_3_3/index.html, then you should choose the article ele-
} ment.

\subsection*{4.3.4 What's the Use of Those Semantic HTML Elements?}

If you've carefully followed this section, you've seen that the semantic HTML elements are very useful. Thus, probably one of their advantages is that they make life easier for you as the developer of the website.

For "normal" visitors, these semantic HTML elements don't have much value at first. On the contrary, those visitors won't even be able to distinguish in the web browser whether you've used div elements or the semantic HTML elements. However, if, for example, a new smart web browser provides special features that let you get to navigation by clicking a button, the new semantics take on meaning for normal visitors as well.
The situation is different, however, for visually impaired visitors who use a screen reader. A good screen reader could "recognize" the content of the web page based on the new semantic structure and thus jump directly to the content or navigation.

Of course, you shouldn't disregard the search engines at all. For example, you could let the search engine know in a consistent and standardized way where which content is located, so that it assigns a higher ranking to the relevant content of a web page.

\subsection*{4.4 HTML Elements for Text Markups}

You apply HTML elements for text markup within plain text for individual letters, words, or parts of sentences. Thus, the described elements don't create a new paragraph or line break, but mark out specific passages in a continuous text according to the semantics defined for the element. You can find all text markups used here in the HTML document /examples/chapter004/4_4/index.html.

\section*{Text Formatting via CSS}

Even though many of the elements presented here cause a slight visual change of the text in the web browser, you shouldn't use these HTML elements for text formatting. CSS is responsible for text formatting. These HTML elements rather serve a clean semantic text markup. Thanks to semantic text markup, you can lay the foundation for later text formatting with CSS. If you use sensible text markup in body text, you can later format your text more easily and logically with CSS.
\begin{tabular}{|l|l|}
\hline HTML Element & Meaning \\
\hline <abbr〉 & Marking abbreviations or acronyms. \\
\hline <cite> & Marking text as source text of a working title. \\
\hline
\end{tabular}

Table 4.4 Brief Overview of the Elements Covered for Text Markups
\begin{tabular}{|l|l|}
\hline HTML Element & Meaning \\
\hline <code> & Marking up computer code within a paragraph of text. \\
\hline <pre> & \begin{tabular}{l} 
Marking up preformatted text. All spaces and line breaks get dis- \\
played as specified in the text.
\end{tabular} \\
\hline <kbd> & Marking up text as keyboard input. \\
\hline <samp> & Marking up text as screen output of a program. \\
\hline <dfn> & Defining a term. \\
\hline <var> & Marking up text as a variable. \\
\hline <bdo> & Changing the text direction for bidirectional text. \\
\hline <bdi> & Defining a section for bidirectional text. \\
\hline <em> & Highlighting text you would emphasize in spoken language. \\
\hline <strong> & terms of content. \\
\hline <i> & \begin{tabular}{l} 
Marking up words or passages with technical terms, thoughts, \\
and foreign words.
\end{tabular} \\
\hline <is & Marking up meaningful names or keywords. \\
\hline <b> & Mighlighting text with a marker. \\
\hline <mark> & Marking up words or passages as cited or spoken text. \\
\hline <q> areneral section within a paragraph of text. \\
\hline <q & Marking up text as small print, such as for copyright information, \\
\hline <u> & Marking
\end{tabular}

Table 4.4 Brief Overview of the Elements Covered for Text Markups (Cont.)

\subsection*{4.4.1 Marking Up Abbreviations or Acronyms Using <abbr>}

The abbr element ( \(a b b r=\) abbreviation) can be used for abbreviations or acronyms. It's also helpful to use the global HTML attribute title in which you write out the abbreviation or acronym so that a web browser can display the full meaning when hovering over it, as you can see in Figure 4.30. This reproduces the code snippet of the following example:
<p>The <abbr title="world wide web">WWW</abbr> is teeming with
abbreviations.
</p>

Abbreviations or acronyms using abbr
The WWLW is teeming with abbreviations.
world wide web

Figure 4.30 The Global "title" Attribute Displays the Meaning of the
Abbreviation "WWW" When You Hover the Mouse Cursor over the Word

Anyone who writes abbreviations between <abbr> and </abbr> is passing useful information to the web browser, language-checking software, translation systems, screen readers, or even the search engines for indexing. The extent to which this information is useful and actually used can't always be predicted. Nevertheless, the abbr element is very useful for logical text markup.

\subsection*{4.4.2 Marking Up Text as the Source of a Working Title Using 〈cite>}

You can use the cite element when you include the title of a book, movie, painting, piece of music, exhibition, and so on in the body text. However, you should only mark up the working title and not the name or main character of the title. Again, you can usually still use the global HTML attribute title to specify more information about the working title when the user hovers over it with the mouse pointer. Most web browsers display everything between <cite> and </cite> in italics.
<p>According to the book <cite>HTML and CSS-The Comprehensive Handbook</cite> it should read:
</p>
...

According to the book HTML and CSS-The Comprehensive Handbook it should read:
In HTML 4.01, this element was also used for short quotations. In new HTML, the semantic meaning has been converted and should now only be used for working titles.

Figure 4.31 In This Example, We Wrote the Working Title of a Book between <cite> and </cite>

\subsection*{4.4.3 Marking Up Computer Code Representation Using <code> and <pre>}

You should use the code element to indicate computer code within body text. Most web browsers often display this area using a monospace font such as Courier, as shown in Figure 4.32, which renders the following code snippet in the web browser:
<h2>Computer code with <code>code</code></h2>
<p>The <code>code</code> element does not contain any attributes.</p> ...

\section*{Computer code representation using code}

The code element does not contain any attributes.
Figure 4.32 The <code> Element Is Suitable for Marking Up Language Elements or Parts of a Source Code of a Particular Language

If you want to format multiple lines of computer code, you should note the code elements in between <pre> and </pre>. The pre element (pre = preformatted) represents preformatted text. In the section between <pre> and </pre>, several whitespace characters won't get combined to one space, but everything is output as it was entered in the editor. Because that section is output in a monospace font, the pre element is very suit able for outputting source text across multiple lines. This isn't to say that <pre> is only suitable for marking up source code. It's therefore recommended that you specify the content between <pre> and </pre> more precisely with appropriate text markup. So, for source code, you should use <code>; for keyboard input, <kbd>; and for displaying a program output, <samp>.

In the following example, the text preformatted between <pre> and </pre> is output as it was written. Specifying <code> and </code> between <pre> and </pre> isn't mandatory, but it makes the text markup even more precise. You can see the following example at execution in Figure 4.33:
<p>Here is a source code snippet of a C program:</p>
<pre><code>\#include \&lt;stdio.h\&gt;
int main(void)
\{
puts("Hello World!");
return 0;
\}</code></pre>
...
Here is a source code snippet of a C program:
\#include <stdio.h>
int main(void)
\(\left\{\begin{array}{l}\text { puts("Hello World!"); } \\ \} \\ \text { return } 0 \text {; }\end{array}\right.\)
Listing 1: Hello World in C

Figure 4.33 The Text Preformatted between <pre> and </pre> Gets Output Exactly as It Was Entered

\section*{The Masking Characters "\&lt;" and "\&gt;"}

To display < or > characters in HTML that aren't to be used as HTML, the character enti ties \&lt; for < and \&gt; for > were used here.

\subsection*{4.4.4 Keyboard Input Using <kbd> and Program Output Using <samp>}

The kbd element (kbd = keyboard) should be used to mark up continuous text as keyboard input. The samp element, on the other hand, should be used for the screen output of programs. Most often, these two elements are also rendered in a monospace font (usually Courier) in the web browser, as you can see in Figure 4.34, which shows the following example running in the web browser:
<p>You can use <kbd>Strg</kbd> + <kbd>A</kbd> to mark up the entire text.</p> <pre>term\#1\&gt; <kbd>gcc -o Wall hello hello.c</kbd>
term\#1\&gt; <kbd>./hello</kbd>
<samp>Hello World!</samp>
term\#1\&gt;</pre>
```

You can use Strg + A to mark up the entire text.
term\#1> gce -o Wall hello hello.c
term\#1>./hell
M}\begin{array}{l}{\mathrm{ Hello World!}}<br>{\mathrm{ term\#1>}}

```

Figure 4.34 The Web Browsers Themselves Decide How to Display the
Text Between <kbd> and <kbd> for Input or <samp> and </samp>

In Figure 4.34, the kbd elements have been made bold, and the samp elements have been made gray by using CSS to help you see what has been used where.

\subsection*{4.4.5 Marking Up Text as a Definition Using 〈dfn>}

Text that you write between <dfn> and </dfn> is supposed to represent a definition. Usually, you mark up a word or a text passage, which you then explain in the text that follows. However, the dfn element shouldn't mark up the definition itself, but the defined term. Let's take a look at a simple example:
<p>A <dfn>smartphone</dfn>-as opposed to a
cell phone-provides more
computer functionality and better connectivity.
</p>

A smartphone-as opposed to a cell phone-provides more computer functionality and better connectivity.

Figure 4.35 In this Paragraph Text, the Term "Smartphone" Was Described, Which Is Why It Was Placed between <dfn> and </dfn>

In common practice, you can also use another element such as <abbr> inside <dfn> and </dfn>, as shown in the following example:
<p>A<dfn><abbr>smartphone<abbr></dfn>-as opposed to a cell phone-provides more
computer functionality and better connectivity.
</p>
..

You can also use the global attribute title inside the opening \(\langle d f n\rangle\) tag. The value of title should be the same as the content of the dfn element.

\subsection*{4.4.6 Marking Up Text as a Variable Using <var>}

You can use the var element to mark up the text in between as a variable. Such a variable can be, for example, part of an application, a mathematical expression, or an identifier of a variable in a programming language:
<p>The radius <var>r</var> is equal to
half the diameter <var>d</var>.
</p>
...

\subsection*{4.4.7 Changing the Text Direction Using <bdo> and <bdi>}

The bdo element (bdo = bidirectional override) allows you to change the text direction. This is useful, for example, when you want to display text that is written from right to left (e.g., Hebrew or Arabic). By default, the text is displayed from left to right. To change the text direction, you must use the global HTML attribute dir. The attribute value rtl makes the text run from right to left, whereas ltr makes it run from left to right.
You don't need to put every Hebrew or Arabic word between <bdo dir="rtl"> and </bdo>. When you use Unicode in HTML, the text direction is usually automatically taken into account according to the language, provided you use a Unicode-capable web browser. You should only use the bdo element if the correct text direction doesn't work.
To illustrate this, here's a code snippet in which in the first paragraph text-a palindrome for fun-was put between <bdo> and </bdo>, and the text alignment was changed via the attribute dir into the value rtl (right to left). The second paragraph, on the other hand, displays the Hebrew word "shalom", which usually doesn't require changing the text direction. You can see the result of these lines in Figure 4.36:
<p><bdo dir="rtl">Never odd or even</bdo></p>
<p>Ш ל 1 - < /p>

> neve ro ddo reveN
> שלום

Figure 4.36 Example Executed with <bdo>
The situation is different in the following HTML lines:
```

<p>1: (as-salaam alaykum)</p>
<p>2: |
<p>Howdy: 3</p>

```

The first two examples would probably not lead to the desired result here. Although as-salaam alaykum in Arabic and shalom in Hebrew are correctly written from right to left, the following colon and number have been given a different writing direction. Originally, this was supposed to look like the third paragraph with Howdy.
Here, the writing behind the Arabic characters continued from right to left, so that the colon and the number behind it also retained the writing direction. Only the translation of the Arabic or Hebrew meaning was reproduced in the correct place.

To be on the safe side, the bdi element (bdi = bidirectional isolation) was introduced for this purpose. Using the bdi element, you can mark up the boundaries of text direction changes in a Unicode-enabled web browser more accurately. Thus, in the preceding example, you only need to put the Arabic or Hebrew characters between <bdi> and </bdi>.

After that, it looks as shown in Figure 4.37:
<p><bdi>>السلام علليك/bdi>: 1 (as-salaam alaykum)</p>
<p><bdi>口 1 ל \(\mathrm{C}<\) </bdi>: 2 (shalom)</p>
<p>Howdy: 3</p>

> :الساخم طنكم: 1 (as-salaam alaykum)
> שלום: 2 (shalom)
> Howdy: 3 (greetings in the rural Southern United States)

Figure 4.37 Thanks to the Containment of the Arabic and Hebrew Script between <bdi> and </bdi>, the Colon and the Decimal Number Now Display after the Script

\subsection*{4.4.8 Emphasizing Text Using <em>, <strong>, 〈i>, and <b>}

To emphasize text, you can use either the em element (em =emphasis) or the strong element. The em element should be used for words or passages that you would emphasize when speaking.
If you want to bring a word or passage more into focus, you should use the strong element. In contrast to the em element, the strong element is used to mark certain places in the text with a special signal or warning effect. The strong element should definitely be used for words or passages that are particularly important in terms of content.
Let's take a look at the following example:
<p><em>Bear</em>! Who the hell is this <em>Bear</em>!</p>
<p><strong>Caution!</strong> <em>Bear</em> could be standing behind you!</p> <p><strong>Delivery date in <strong><em>summer 2022</em></strong></strong></p> .

In this example，it＇s semantically clear from the emphasis on bear in the first paragraph in Figure 4.38 that it isn＇t the animal that is referred to here，but a person with the sur－ name＂Bear＂．In the second paragraph，the word Caution！was marked with a special importance．In the last paragraph，an em element was nested within a strong element to emphasize summer 2022 more strongly in terms of content in addition to its particular importance．

Bear！Who the hell is this Bear！
Caution！Bear could be standing behind you！
Delivery date in summer 2022
Figure 4．38 Different Ways to Emphasize or Highlight a Text Using＜em＞and＜strong＞
Here，you could also still nest the same HTML elements to increase the emphasis or importance of em or strong elements，at least semantically．
Because web browsers usually render＜em＞with italic and＜strong＞with bold font，you shouldn＇t make the mistake of replacing these elements with＜i＞and＜b＞，respectively， because these elements（i．e．，＜em＞and＜i＞or＜strong＞and＜b＞）are rendered quite simi－ larly in the web browser．As mentioned at the beginning，HTML isn＇t used to format the text，but these HTML elements are about giving the text a meaningful significance．
The i element is recommended to mark special technical terms，a thought，scientific names，or foreign language words．The belement，on the other hand，should be used for meaningful names or keywords to draw attention to something．

\section*{Using＜i＞and＜b＞}

Standard HTML recommends using the b or i elements only if no other HTML tag fits to mark up the text or passage．The days when these elements were used purely for for－ matting are over because CSS is used for that purpose．
＜p＞In 2021，profits have increased by
＜mark＞100 percent＜／mark＞．
＜／p＞
＜p＞Here is a source code snippet of a C program：＜／p＞
＜pre＞＜code＞\＃include \＆lt；stdio．h\＆gt；
int main（void）
\｛ ＜mark＞puts（＂Hello world！＂）；＜／mark＞
return 0；
\}</code></pre>
．．．
```

In 2021, profits have increased by 100 percent.
Here is a source code snippet of a C program:
\#include 〈stdio.h〉
int main(void)
\{ puts("Hello world!");
puts (Hell
return 0 ;
3

```

Figure 4．39 Web Browsers That Recognize the New Element Usually Mark the Text Placed between＜mark＞and＜／mark＞with Yellow Background Color

Even though the mark element predominantly applies yellow background color to the text，you shouldn＇t use it to apply a background color to a text．You should rather use ＜mark＞only if it makes sense in terms of content and no other semantic HTML element is suitable．If you want to format the text background，you should use the span element （Section 4．4．17）with CSS instead．

\section*{4．4．10 Placing Text between Quotes Using 〈q＞}

While you can use the blockquote element to quote an entire paragraph text，the \(q\) ele－ ment allows you to quote something in the middle of the text or mark it as spoken text． Text or passages you insert between \(\langle q\rangle\) and \(\langle/ q\rangle\) should be placed between quotes by the web browser．You shouldn＇t use the \(q\) element if you simply want to enclose a word or passage in quotation marks．That wouldn＇t be the semantic sense of the q element．

If you use a quote or spoken text from another source，you can use the cite attribute with a URL to the source．Because the implementation of the cite attribute is still poor in web browsers，you may want to consider using a hypertext link．

You can also nest the \(q\) element．Such nested \(q\) elements usually get another matching quotation mark．In this country，for example，the outer quotation marks are double and the inner ones are single．This is demonstrated in the following example，the exe－ cution of which you can see in Figure 4．40：
＜p＞Wolf asked：＜q cite＝＂http：／／tom－bear．com／＂＞
＜em＞Bear＜／em＞！Who the hell is this＜em＞Bear＜／em＞！＜／q＞
＜／p＞
＜p＞Fox replied：＜q＞Caution！＜q＞＜em＞Bear＜／em＞＜／q＞could be standing behind you！＜／q＞
＜／p＞

As you can see in Figure 4．40，this example quoted spoken text in the first paragraph The second paragraph demonstrates the nesting of \(q\) elements．The inner \(q\) element was placed between single quotes and the outer one between double quotes．

\section*{Placing text between quotes using \(\mathbf{q}\)}

Wolf asked：＂Bear！Who the hell is this Bear！＂
Fox replied：＂Caution！＇Bear＇could be standing behind you！＂
Figure 4．40 Placing Text between Quotes Using the \(\langle q\rangle\) Element

\section*{For Advanced Users：Setting Custom Quotation Marks}

The problem with the \(q\) element is that the quotes set by the web browser may not always be the ones you want．In this case，an intervention with CSS is a good idea．Thus， the following CSS line could be used to change the first and second nested characters of the \(q\) element：
q \｛quotes：＇»＇＇«＇＇ゝ＇＇く＇；\}

\section*{Placing text between quotes using \(\mathbf{q}\)}

Wolf asked：» Bear！Who the hell is this Bear！
Fox replied：»Caution！»Bear＜could be standing behind you！«
Figure 4．41 The Quotes of the＜q＞Element Have Been Changed with CSS

\section*{4．4．11 Underlining or Crossing Out Text Using 〈u〉 and 〈s＞}

Both the \(u\) element（ \(u=\) underline）and the \(s\) element（ \(s=\) strikethrough）were marked as deprecated with HTML 4.01 and were supposed to be removed from the standard．With
the new HTML standard，they have acquired a new semantic meaning and are thus again an official part of HTML．

You should use the s element to mark content as obsolete or no longer correct．The web browsers display the text between \(\langle\mathrm{s}\rangle\) and＜／s＞as strikethrough．If you want to display a document edit where you want to mark a word or passage from the not yet finished document as deleted，you should use the del element instead．
According to its new meaning，the u element is to be used for underlining proper names， as is common，for example，in Chinese writing（see http：／／en．wikipedia．org／wiki／ Proper＿name＿mark）．Most readers are unlikely to use Chinese proper names，so another recommended example of the \(u\) element is to knowingly indicate misspelled words or passages containing errors．Web browsers usually display the u element with an underscore．In addition to the \(u\) element，there＇s the ins element，which is also ren－ dered as underlined but is intended to indicate newly inserted content（Section 4．4．12）． Here＇s a short example，the execution of which you can see in Figure 4．42：
＜p＞You can place a text in the middle with
＜s＞＜code＞\＆lt；center\＆gt；＜／code＞or＜／s＞the
CSS feature＜code＞text－align＜／code＞and the value
＜var＞center＜／var＞．
＜／p＞
＜p＞我来自
〈u＞德国
＜／u＞。＝I am from Germany．＜／p＞
＜p＞Also，＜u class＝＂spell－checker＂＞spellig errors＜／u＞
can be marked with it．
＜／p＞
．．＞
As you can see in Figure 4．42，in the first paragraph text，the content＜center＞or was crossed out．In the second paragraph text，a Chinese proper name（Germany＝德国）is underlined．Finally，in the final paragraph，a spelling error was underlined with a red dashed line．The color changes and the style of the underline were adjusted with CSS in the example．

\section*{Underlining or crossing out text using \(s\) and \(u\)}

You can place a text in the middle with the CSS feature text－align and the value center．

我来自德国。＝I am from Germany
Also，spellig errors can be marked with it．
Figure 4．42 Underlining or Crossing Out Text Using＜u＞and 〈s＞

In any case, it's important that you use both elements for their intended content and not for text decoration. If you want to underline or strike through text for purely decorative reasons, you should use CSS to do so.

\subsection*{4.4.12 Marking Changes of Text Using <ins> and <del>}

The ins element is rendered by web browsers similar to the u element, while the del element is rendered similar to the s element. Nevertheless, the semantic meaning of the two elements is different and therefore not interchangeable.
The del element (del = delete) allows you to mark a content-related (active) editing of a text as deleted in the revised sense. It's used to inform readers that this part has been revised or further developed. Instead of removing the text completely, you want to make sure that the previous versions of the text remain visible. The web browser usually crosses out this text.
The ins element (ins = insert) is the counterpart of the del element and should be used when something new gets inserted into the document. Here again, you mark a further development of the previous version of the text. The web browsers usually display this text with an underscore.

You can see the execution of the following example with the elements del and ins in Figure 4.43.
...
<del>
<p>The singer performs on \(1 / 1 / 2024\) in the concert hall!</p>
</del>
<ins>
<p>The concert was canceled,
because the singer is sick!</p>
</ins>
...

\section*{Marking changes of text using del and ins \\ The concert was canceled, because the singer is sick!}

Figure 4.43 The <del> Element Used to Delete a Paragraph Text and Insert a New Paragraph with a New Message between <ins> and </ins>

Again, you should use the del and ins elements only if they fit the semantics. If you want to cross out or underline the text in a purely decorative way, CSS should be the first choice.

\section*{Text Underline Can Be Confusing!}

The frequent use of underscores with <ins〉 or <u> may confuse the user because hypertext links with <a> are usually also represented with an underscore. It's therefore also recommended to change the formatting with CSS, so that the individual elements are displayed in a clearly distinguishable manner.

\subsection*{4.4.13 Displaying Text as Superscript or Subscript Using <sup> and <sub>}

These two markups are mainly used for simple mathematical and chemical formulas to lower text with the sub element (sub = subscript) and to raise it with the sup element (sup = superscript).
Here's a code snippet as an example, the execution of which you can see in Figure 4.44
<p><sup>[1]</sup> Reaction scheme: 2 H<sub>2</sub>0
\&RightArrow; 2 H<sub>2</sub> + 0<sub>2</sub></p>
<p><sup>[2]</sup> Calculate circular area: \(A=\& p i ; * r\) <sup>2</sup></p>
...

\section*{Displaying text as superscript or subscript using sub and sup}

Figure 4.44 The <sub> and <sup> Elements Were Used Several Times for Superscript and Subscript Numbers and Footnotes, Respectively

\subsection*{4.4.14 Marking Dates and Times Using <time>}

The time element was introduced to mark up dates and times. When displayed in a web browser, text placed between <time> and </time> is usually not visually noticeable at all. The goal and purpose of the time element is rather that date and time are uniquely coded for machines and can also be displayed in a readable way for humans. You can specify the machine-readable form in the HTML attribute datetime, while the humanreadable form is usually written between <time> and </time>. Here's a brief example:
```

<p>We met on my <time datetime="2023-11-12">
    44th birthday</time> at <em>Bear's place</em>.
    <time datetime="20:00">at 8 pm.</time>
</p>
```

The specification 44th birthday can be any other text such as Wednesday or November 12 as long as the value of datetime is a precise date of the Gregorian calendar. The same applies to the time at 8 pm .

\section*{Valid Machine-Readable Date and Time Information}

A date readable by machines is specified as YYYY-MM-DD. YYYY is the year (e.g., 2023), MM is the month (e.g., 11 for November), and DD is the day in the month (e.g., 12). If you also want to note the time, you must place a capital \(T\) between the date and the time and then enter the time behind it in the form HH:MM where HH stands for hours and MM for minutes. In a newer version of time, this T can be omitted and a space can be used instead. Optionally, you can specify the time zone offset from UTC (Coordinated Universal Time). UTC is a designation for Universal Time. Here, you must specify a + followed by HH:MM, for example
2023-10-10T21:00+01:00
For this example, you enter October 10,2023 , as the date. The time is exactly 9 pm , and the \(+01: 00\) at the end means UTC +1 hour. Many other different forms of presentation are possible in this context. For more information, you should visit www.w3.org/TR/ 2011/WD-htm/5-20110525/text-level-semantics.html\#the-time-element. For further and future developments of the time element, you may find the following website useful: http://wiki.whatwg.org/wiki/Time_element.

Alternatively, you can specify the date, time, and time zone (if needed) in datetime at once:
<p>We met on my
<time datetime="2023-11-12T20:00+00:00">44th birthday
</time> at <em>Bear's place</em> at 8 pm .
</p>

So, if you use a valid datetime attribute with the time element, you can write whatever you want between <time> and </time>. Without specifying the datetime attribute, you must specify a valid date format and/or a valid time format-that is, the machinereadable version-between <time> and </time>, such as the following:
<p>We met on <time>2023-11-12</time> at <em>Bear's place</em> at <time>20:00</time>
</p>

The time element has been improved and made much more flexible over time after its first release. For example, the following specifications are also possible:
<p>On every <time datetime="11-12">birthday</time> I got flowers.
</p>
.
This refers to November 12. Another option would be to specify the following for datetime if you don't remember the exact day of the date:
<p>The concert in the photo was recorded sometime in
<time datetime="2023-08">August</time>
this year.
</p>
Here, a date in August 2023 is meant. It's possible to use only the year (e.g., datetime= "2023").
Another improvement is that you can use a time duration. Here's an example of how such a duration is represented:
<p>the rock festival lasted <time datetime="P3D">3
days</time>.
</p>
The letter P stands for period, the D for day, and the 3 for three days. You can still specify a time period from a combination with H for hours, M for minutes, and S for seconds (e.g., datetime="P1D5H10M" = 1 day, 5 hours, and 10 minutes).

\section*{Here's What Doesn't Work (Yet)!}

It isn't yet possible to specify a time before Christ ( BC ), neither can you specify a time period based on two date ranges. For this purpose, you still need to use two time elements.

\section*{What Should I Use <time> for in Practice?}

If you use the time element, it will be easier for other programs to index this data. For example, it's easier for a script in blog articles to extract the date using the time element, rather than using any other techniques to look for and read this data. By having the date and/or time information in a machine-readable form, there's the advantage for search engines to make use of it when searching for items of a certain period or date.

If you then also use the datetime attribute, you can provide readers with a reader friendly alternate display between <time> and </time>. Basically, you should put a (readable) date and/or time between <time> and </time> because the web browser won't dis play an automatic value in between if you don't put anything there.
Another possibility is that future web browsers provide the option to enter a date into the calendar at the request of the visitor. In addition, the web browser could convert the time used into the visitor's time zone if the appropriate value was specified with datetime. And he could convert the season according to the Buddhist time calculation, which is valid, for example, in Thailand or Laos
In Figure 4.45, you can see again all time elements described and used here. I underlined the places where <time> was used with a dotted line using CSS for better visibility. Here, the date on which the article was written was additionally indicated behind the article title. To use the time element in a semantically correct way, the specification of an exact time must be used and observed. For example, you should avoid the following incorrect usage:

These are the results from <time>last week</time>.

\section*{Marking dates and times using time}
1. August 2023

We met on my 44th birthday at Bear's place. at 8 pm .
We met on my 44th birthday at Bear's place at 8 pm .
We met on 2023-11-12 at Bear's place at 20:00
On every birthday I got flowers.
The concert in the photo was recorded sometime in August this year
The rock festival lasted 3 days.
Figure 4.45 To Clarify What Is between <time> and </time>, a Dotted Underline Has Been Added

\subsection*{4.4.15 Marking the Small Print Using <small>}

You should use the small element for words or text passages in which you want to display some small print. This can be copyright information, license information, legal notes, and so on.

Here's a short code snippet with the small element; its execution is shown in Figure 4.46 .
...
<article>
<header>
<h2>Small print with small</h2>
<small>\&copy; John Doe;
<time datetime="2024-01-01">January 1, 2024</time></small>
</header>
<p>The shipment can be delivered in <time datetime="P2D">2 days</time>
<small>(Due to high demand
it can also take longer (+1 day)).</small>
</p>
</article>
...
Again, you should use this element only if it semantically fits the content and not to make text look smaller. For visual adjustments, you should use CSS.

\section*{Small print with small}
© John Doe; January 1, 2024
The shipment can be delivered in 2 days. (Due to high demand it can also take longer ( +1 day)).
Figure 4.46 A Copyright Was Placed in the Head of an Article as well as Small Printed nformation between <small> and </small>

\subsection*{4.4.16 Using <ruby>, <rp>, and <rt> for Annotations about Pronunciation}

The Ruby annotation is probably of little interest to most readers. This is an annotation system in which the text appears with the annotation in one line, as used in Japanese and Chinese texts. If you want to know more about this notation, see https://en.wikipedia.org/wiki/Ruby_character.

Here, we'll only briefly describe the use of the Ruby annotation with the existing HTML elements. For this purpose, here's a simple example in which Asian characters have been omitted:
```

...
<ruby>
LOL<rp>(</rp><rt>Laugh Out Loud</rt><rp>)</rp>
</ruby>
</p>
...

```

\section*{ruby, rt und rp for annotations about the pronunciation}

\section*{Laugh Out Loud \\ LOL}

Figure 4.47 The Text between a Ruby Annotation Is Displayed as Text with Annotation in One Line

The example features LOL with annotations (which is nonsense here, of course). All characters, including annotations, are written between <ruby> and </ruby>. Then the character is noted as element content (here: LOL). The parentheses of the annotations are created with the (optional) rp element ( \(\mathrm{rp}=\) Ruby parenthesis). The text is then marked with the rt element ( \(r t=\) Ruby text \()\). Thus, the annotation is written between \(\langle r t\rangle\) and \(</ r t\rangle\).

\section*{ruby, it und rp for annotations about the pronunciation}

\section*{LOL (Laugh Out Loud)}

Figure 4.48 The Optional <rp> Element Is Used to Put Parentheses around the Ruby Text (with the <rt> Element) for Web Browsers That Don't Understand <ruby>
```

Web Browser Support for <ruby>
Web browser support in current web browsers is now quite good. In some web brows-
ers, however, an add-on may need to be installed.

```

\subsection*{4.4.17 Grouping Ranges of Individual Text Passages Using <span>}

While you can use the div element (Section 4.2.7) to group entire groups into one block, you can use the span element to mark up individual passages of text inside the body
text with CSS. Visually, text placed between <span> and </span> doesn't change at all. In addition, the span element in conjunction with a JavaScript is quite useful when searching for global attributes used within it to directly update the element content. Here's a rather theoretical example:
<p>Current temperature <span id="temp">64</span> F</p>
Here, you could use a JavaScript to read the global id with the value temp and further process or update the element content. Let me also show you this CSS example:
<p>Formatting with <span style="text-decoration:overline;">
CSS</span> and the span element.</p>
Here, the text is preceded by a stroke that has been implemented via style statements directly in the HTML tag span with the HTML attribute style.

\section*{Grouping ranges of individual text passages using span}

Current temperature 64 F
Formatting with \(\overline{\mathrm{CSS}}\) and the span element.
Figure 4.49 The <span> Element Has No Default Formatting; Besides Designing with CSS, It Can Also Be Used to Identify Unique Elements.

However, as with the div element, you should only use this element if there's no semantically more suitable HTML element available.

\section*{Example of All Text Markup Elements}

Once again, note that you can find an example with all the text markup elements demonstrated here on the web page for the book (www.rheinwerk-computing.com/ 5695/) and at https://html-examples.pronix.de/examples/chapter004/4_4/index.html.

\subsection*{4.5 Related Topic: Character Encoding}

What follows here isn't a treatise on character encoding in general, but rather in the context of HTML documents - especially on how you can avoid special characters, such as German umlauts, from getting displayed as cryptic characters. If you consider the following two points, there shouldn't be any problem:
- In the HTML document, you need to specify the character encoding of the document in the head data between <head> and </head>, as we've been doing in the book so far with <meta charset="UTF-8">. Unless you have a specific reason, you should always use the UTF-8 value for the charset attribute.
- However, it doesn't suffice to specify the character encoding in the HTML document as it must also be saved in this encoding using the editor of your choice. Consequently, if you've specified UTF-8 as the character encoding in the HTML document, you must also save the document with the UTF-8 encoding. With most editors, you no longer have to bother about this. Nevertheless, it should be briefly mentioned here

\subsection*{4.5.1 From Bytes to Character Encoding}

The smallest unit, the bit, will be skipped here because you don't need to go so deep into detail at this point. The byte unit is quite sufficient for this purpose. When the computer reads a file or data into the main memory, it's basically just bytes that have a certain value. The value of a single byte results from the states of the individual bits. Let's use a byte with the value 68 (incidentally, with the bit value 1.000.100) as an example.

To create a human-readable character from this byte with the value 68, a convention is needed that describes which byte value corresponds to which representable character. For this purpose, a translation table (also referred to as encoding table) is used for encoding bytes.

\subsection*{4.5.2 From ASCII to ISO-8859}

You know that an encoding table is responsible for turning a byte into a readable character. The first type of such a character set was introduced with the ASCII encoding and the EBCDIC encoding, with which 128 different states can be represented on 7 bits. ASCII encoding has become established in common practice. In the ASCII encoding table, the first 32 characters are pure control characters, and the actual characters are stored in the character set between 32 and 127. A look at the ASCII encoding table shows that the value 68 corresponds to the capital letter D.

The 8th bit was initially used only for error-correction purposes (parity bit) for communication lines or other control tasks. Because there was no space left in the ASCII character set between the values 32 and 127 for language-specific characters (e.g., umlauts), the 8th bit was used to extend the character set. At this point, the Babylonian character confusion also arose because different developers wrote their own "8th-bit-codes." IBM PCs and English MS-DOS systems used codepage 435, for example. In Germany, codepage 850 was used for Western European characters.
Newer standards such as ISO-8859 also use 8 bits. Here, several character set tables were developed at once. For example, ISO-8859-1 (or Latin-1) represents the Western European languages. The first 127 characters were taken over from the ASCII encoding. In the
values between 128 and 255, many special characters and important characters from different European languages were implemented (with the German umlauts, the Spanish tilde character, or the French accent characters).

So, theoretically, you can use the ISO-8859-1 character set for the HTML document:
<meta charset="iso-8859-1">
While in theory, you can use any character set for charset, you should keep in mind that not every web browser understands all character sets. If you use a more widely used character set, you have a better chance that a web browser in distant countries will be able to do something with it.
Microsoft had also added its own variation to the ISO-8859-1 encoding with codepage 1252. After all, code page 1252 already contained the euro sign. ISO-8859-1, on the other hand, doesn't recognize the euro sign because at the time this table was created, the euro didn't even exist. The euro sign was added by the ISO only later with ISO-8859-15. Now the situation here is that ISO-8859-1 doesn't recognize the euro sign, while ISO-8859-15 and codepage 1252 do know it, but the value in the encoding table is again different. Fortunately, today you don't need to deal with the different character sets of a language. The description of the ISO 8859 standards here serves only as background information on the subject.
The current HTML specification uses the Unicode UTF-8 character set with charset= "UTF-8".

\subsection*{4.5.3 Beyond the Byte Boundary with Unicode}

The preceding provided a good impression of the confusion regarding the different character encodings. Note, however, that this was only about the Western European character set, and I haven't really gone into detail yet. The fact is that character encoding can be relatively complex if you pack everything into a byte and then want to use different characters from different cultures. To bring all characters under one hood, the Unicode system was introduced.
The Unicode character set can be used to represent all human-made characters. In purely theoretical terms, more than four billion characters could be used with 32 bits per character-in practice, Unicode is limited to about one million code points. UTF-8 is the 8-bit encoding of Unicode, which is also backward compatible with ASCII encoding. A character can contain between one and four 8 -bit words. UTF-8 is now a uniform standard. For example, many operating systems use UTF-8 by default, and UTF-8 is also being used increasingly in web development with HTML to represent language-specific characters, where it more and more replaces the use of HTML entities (Section 4.6).

\section*{More Information Online}

I could write much more on this topic, especially Unicode, but this would go beyond the scope of this book. For more information, visit http://r12a.github.io/scripts/tutorial/ and https://home.unicode.org/. You can also find the characters of the Unicode encoding at www. unicode.org/charts/.

\subsection*{4.6 Character Entities in HTML}

While the importance of character entities in HTML has diminished considerably with the gradual spread of Unicode (especially UTF-8), I should still touch on them briefly here because there are always reasons to use them. In Section 4.5, you learned about different character sets, and, by now, you know how to specify the character set used as a <meta> tag in the HTML document head with charset. For example, if you've specified ISO-8859-1 or ISO-8859-15 as the character set and want to use the word shalom (שלום) in Hebrew characters, you're likely to be unsuccessful:
<meta charset="iso-8859-1">
<p>Shalom: 1 ל ל 1 </p>
The output is likely to be a cluster of cryptic characters instead of שלום. The simplest solution would be to change the character set to UTF-8 via
<meta charset="UTF-8">
There might also be a different problem with this example: How do you type the word in your editor? If you don't happen to have a Hebrew keyboard in front of you or a virtual keyboard with Hebrew characters, the simple and quick solution might be to use the character entities of HTML. This is how you write the word "Shalom" in Hebrew using character entities:
<p>Shalom: <bdo>\&\#1501;\&\#1503;\&\#1500;\&\#1513;</bdo></p>

\subsection*{4.6.1 Structure of a Character Entity in HTML}

As you've seen before from the four Hebrew characters, an HTML entity starts with the \& character and ends with the semicolon. Now you have two options to arrange the sign:
- Numeric entities

You specify the form with \&\#nnn;. Here, nnn stands for the encoding of the character. This form is used when it isn't possible to enter the character via the keyboard. The
notation can also be in the form of \&\#xhhh; where xhhh is the hexadecimal value for the character. The notation without x is the decimal notation.

\section*{- Named entities}

This is an easier-to-remember name that has been agreed on for the character. You may have already seen examples with \&lt ; (lt = less than) or \&gt; (gt = greater than) where people prefer to use these named entities. Alternatively, you can use the numeric entity instead of the named entities. For example, with \&1t;, \&\#60; , and \&\# \(\times 003 C\); , you would use the < sign (less-than sign) three times.

\section*{Masking HTML-Specific Characters}

Especially if you use special characters in your body text that are part of the HTML syn tax, you should mask these characters by using the appropriate entity. For example, the following line is likely to cause display problems in a web browser:
<p>Mexico City<Tokyo and Mumbai>London</p>
The web browsers would only output Mexico City-London here, because the area between < and > is considered an HTML element (even if it's wrong). Although you could solve this problem with a blank line in between, you should use the appropriate entity for this, to be on the safe side. This is where the named entity comes in handy:
<p>Mexico City\&lt;Tokyo and Mumbai\&gt;London</p>
The ampersand character \& belongs to it as well and should be used via the string \&amp; in the continuous text.
In addition, if you want to use the double quote within HTML attributes, you should replace " with \&quot; , such as the following
<img src="\#" alt="Cover of book \&quot;CSS from A to Z\&quot;">
In the alt attribute, \&quot; was used as a masking character for ". If you used " instead of the named entity \&quot; here, the area in between would probably be "swallowed" by the web browser.

\section*{More Unicode Numbers}

You can find even more Unicode numbers for a desired character at www.unicode.org/ charts.

\subsection*{4.7 Summary}

In this chapter, you learned a lot about the semantic use of various HTML elements. Roughly summarized, you've learned the following in this chapter:
- How to use the <section>, <article〉, <aside>, and <nav> elements to divide an HTML document into meaningful parts (or sections)
- How to use headings with the elements <h1> to <h6> and the new section elements <section>, <article>, <aside>, and <nav> to affect the content structure of headings
- How to use a header with <header> and a footer with <footer> in an HTML document
- How to use the <main> element to set the main content of a web page
- Which HTML elements are available to divide or group plain text content into paragraphs
- What semantic HTML is and how you can structure a semantic web page
- How to logically mark up text, individual letters, words, or parts of sentences to give them semantic meaning
- That the HTML elements for text markup aren't used for formatting web pages, but that this is done via CSS

1.7 Summary ..... 53
2 Basic Structure of HTML and HTML Documents ..... 55
2．1 Syntax and Structure of HTML and HTML Documents ..... 55
21．1 How to Structure a Document in HTML ..... 55
2．1．2 Viewing the Tree Structure Using the Document Object Model Inspector ..... 58
2．1．3 HTML Tags and HTML Elements ..... 59
2．1．4 Nesting HTML Elements and the Hierarchical Structure ..... 60
2．1．5 Avoiding Incorrect Nesting of HTML Element ..... 61
2．1．6 Omitting the End Tag of an HTML Element ..... 62
2．1．7 Standalone HTML Tags without End Tags ..... 63
2．1．8 Additional HTML Attributes for HTML Elements ..... 64
2．1．9 Using Comments in HTML Documents ..... 65
2．2 A Simple HTML Document Framework ..... 65
2．2．1 HTML Document Type：＜！doctype＞ ..... 66
2．2．2 Beginning and Ending an HTML Document：＜html＞ ..... 67
2．2．3 Head of an HTML Document：＜head＞ ..... 67
2．2．4 Visible Part of an HTML Document：＜body＞ ..... 68
2．3 Summary ..... 68
3 Head Data of an HTML Document ..... 69
3．1 Overview of HTML Elements for the Head ..... 69
3.2 ＜title＞：Heading of the HTML Page ..... 70
3．3 Related Topic：Naming Convention and Referencing ..... 72
3．3．1 Valid and Good File Names for an HTML Document ..... 72
3．3．2 Valid Directory Names and Meaningful Directory Structures ..... 73
3．3．3 Writing a Reference to a Data Source ..... 73
3．4 Defining the Base URL of a Web Page Using＜base＞ ..... 76
3．5 Referencing an External Document via＜link＞ ..... 78
3．6 Writing Document－Wide CSS Styles Using 〈style〉 ..... 81
3．7 Including Scripts in Web Pages Using 〈script〉 ..... 82
3．8 Metadata for the Document Using＜meta＞ ..... 85
3．8．1 The Most Commonly Used Metadata ..... 85
3．8．2 Setting the Viewport ..... 87
3．8．3 Specifying Useful Metadata for a Web Crawler88
3．8．5 Useful Metadata for the Web Browser ..... 90
3．8．6 Using General Metadata ..... 91
3．8．7 My Recommendation：This Metadata Belongs in the Basic HTML Framework ..... 92
3．8．8 HTML Attributes for the＜meta＞Element ..... 92
3．9 Summary ..... 93
4 The Visible Part of an HTML Document ..... 95
4．1 HTML Elements for Structuring Pages ..... 95
4．1．1 Using＜body＞：The Displayable Content Section of an HTML Document ..... 96
4．1．2 Introducing the Section Elements of HTML ..... 96
4．1．3 Using Headings with the HTML Elements from＜h1＞to＜h6＞ ..... 104
4．1．4 Creating a Header Using＜header＞and a Footer Using＜footer＞ ..... 108
4．1．5 Marking Contact Information Using＜address＞ ..... 110
4．2 HTML Elements for Structuring Tex ..... 111
4．2．1 Adding Text Paragraphs Using＜p＞ ..... 112
4．2．2 Forcing Line Breaks Using＜br＞ ..... 113
4．2．3 Adding Optional Line Breaks Using＜wbr＞ ..... 114
4．2．4 Forcing Spaces and Preventing Wrapping Using＂\＆nbsp；＂ ..... 115
4．2．5 Adding a Topic－Based Separation Using＜hr＞ ..... 116
4．2．6 Adding Paragraphs or Citations Using 〈blockquote＞ ..... 117
4．2．7 Defining a General Section Using＜div＞ ..... 118
4．2．8 Using＜main＞：An HTML Element for the Main Content ..... 120
4．2．9 Labeling Content Separately Using＜figure＞and＜figcaption ..... 121
4．2．10 Creating Unordered Lists Using＜ul＞and 〈li＞ ..... 122
4．2．11 Creating Ordered Lists Using＜ol＞and＜li＞ ..... 123
4．2．12 Reversing the Numbering of an Ordered List ..... 124
4．2．13 Changing the Numbering of an Ordered List ..... 124
4．2．14 Nesting Lists within Each Other ..... 125
4．2．15 Creating a Description List Using 〈dl＞，＜dt＞，and＜dd＞ ..... 128
4．3 Using Semantic HTML ..... 130
4．3．1 HTML without a Precise Structure ..... 130
4．3．2 Generic Structuring Using＜div＞ ..... 132
4．3．3 Semantic Structuring Using the Elements Provided in HTML ..... 135
4．3．4 What＇s the Use of Those Semantic HTML Elements？ ..... 138
4．4 HTML Elements for Text Markups ..... 138
4．4．1 Marking Up Abbreviations or Acronyms Using＜abbr＞ ..... 140
4．4．2 Marking Up Text as the Source of a Working Title Using＜cite＞ ..... 140
4．4．3 Marking Up Computer Code Representation Using＜code＞ and＜pre＞ ..... 141
4．4．4 Keyboard Input Using 〈kbd＞and Program Output Using 〈samp〉．．． ..... 142
4．4．5 Marking Up Text as a Definition Using＜dfn＞ ..... 143
4．4．6 Marking Up Text as a Variable Using＜var＞ ..... 144
4．4．7 Changing the Text Direction Using＜bdo＞and＜bdi＞
4．4．8 Emphasizing Text Using＜em＞，＜strong＞，＜i＞，and＜b＞ ..... 145
4．4．9 Highlighting Text Using＜mark＞ ..... 146
4．4．10 Placing Text between Quotes Using 〈q＞ ..... 147
4．4．11 Underlining or Crossing Out Text Using＜u＞and 〈s〉 ..... 148
4．4．12 Marking Changes of Text Using＜ins＞and＜del＞ ..... 150
4．4．13 Displaying Text as Superscript or Subscript Using＜sup＞and＜sub＞． ..... 151
4．4．14 Marking Dates and Times Using＜time＞ ..... 151
4．4．15 Marking the Small Print Using＜small＞ ..... 155
4．4．16 Using 〈ruby＞，＜rp＞，and＜rt＞for Annotations about Pronunciation ..... 155
4．4．17 Grouping Ranges of Individual Text Passages Using 〈span〉 ..... 156
4．5 Related Topic：Character Encoding ..... 157
4．5．1 From Bytes to Character Encoding ..... 158
4．5．2 From ASCII to ISO－8859 ..... 158
4．5．3 Beyond the Byte Boundary with Unicode ..... 159
4．6 Character Entities in HTML ..... 160
4．6．1 Structure of a Character Entity in HTML ..... 160
4．7 Summary ..... 161
5 Tables and Hyperlinks ..... 163
5．1 Structuring Data in a Table ..... 163
5．1．1 A Simple Table Structure Using＜table＞，〈tr＞，〈td＞，and 〈th＞ ..... 164
5．1．2 Combining Columns or Rows Using＂colspan＂or＂rowspan＂ ..... 166
5．1．3 HTML Attributes for the Table Elements ..... 169
5．1．4 Structuring Tables Using＜thead＞，＜tbody＞，and 〈tfoot＞ ..... 169
5．1．5 Grouping Columns of a Table Using＜colgroup＞and＜col＞ ..... 172
5．1．6 Labeling Tables Using＜caption＞or＜figcaption＞ ..... 174
5．2 Electronic References（Hyperlinks）Using＜a＞ ..... 177
5．2．1 Inserting Links to Other HTML Documents on Your Own Website ．．． ..... 178
5．2．2 Inserting Links to Other Websites ..... 181
5．2．3 Opening Links with the＂target＂Attribute in a New Window ..... 183
5．2．5 Setting Links to Other Types of Content ..... 185
5．2．6 Adding Download Links Using the＂download＂Attribute ..... 186
5．2．7 Setting Links to Specific Parts of a Web Page ..... 188
5．2．8 Creating Links to Phone Numbers ..... 191
5．2．9 HTML Attributes for the HTML Element＜a＞ ..... 192
5．3 Summary ..... 193
6 Graphics and Multimedia ..... 195
6．1 Embedding Images Using＜img＞ ..... 196
6．1．1 Adding Images to an HTML Document ..... 196
6．1．2 Specifying the Height and Width of a Graphic ..... 200
6．1．3 Labeling Images Using＜figure＞and＜figcaption＞ ..... 202
6．1．4 HTML Attributes for the HTML Element＜img＞ ..... 204
6．2 Creating Link－Sensitive Graphics（Image Maps） ..... 204
6．2．1 Use HTML Attributes for the HTML Element＜area＞ ..... 207
6．2．2 Referencing Defined Areas of the HTML Element＜area＞ ..... 208
6．2．3 HTML Attributes of 〈area＞ ..... 208
6．3 Loading the Appropriate Image Using＜picture＞ ..... 210
6．3．1 HTML Attributes of＜source＞ ..... 211
6．3．2 Multiple Image Sources with the HTML Attribute＂srcset＂ ..... 212
6．4 Adding an Icon for the Website（Favicon） ..... 213
6．5 Using Vector Graphics in HTML Documents ..... 214
6．5．1 Adding SVG as a Graphic Reference Using＜img＞ ..... 215
6．5．2 Embedding SVG Directly into the Web Page Using＜svg＞ ..... 216
6．5．3 SVG Tags for Vector Graphics ..... 217
6．5．4 Overview of Graphical SVG Elements ..... 217
6．5．5 Further Notes on Using SVG ..... 219
6．5．6 Mathematical Formulas Using MathML ..... 219
6．6 Drawing Graphics Using＜canvas＞ ..... 221
6．7 Playing Videos Using the HTML Element＜video＞ ..... 222
6．7．1 HTML Attributes for the HTML Element＜video＞ ..... 224
6．7．2 Adding Subtitles to a Video Using＜track＞ ..... 225
6．7．3 Playing Videos via YouTube ..... 228
6．8 Playing Audio Files Using the HTML Element＜audio＞ ..... 229
6．8．1 HTML Attributes for the HTML Element＜audio＞ ..... 230
6．9 Including Other Active Content ..... 231
6．9．1 HTML Element＜embed＞ ..... 232
6．9．2 HTML Element＜object＞ ..... 232
6．9．3 HTML Element＜iframe＞ ..... 233
6．10 Summary ..... 235
7 HTML Forms and Interactive Elements ..... 237
7．1 Defining a Space for Forms ..... 238
7．2 HTML Input Fields for Forms ..... 239
7．2．1 A Single－Line Text Input Field Using＜input type＝＂text＂〉 ..... 240
7．2．2 A Password Input Field Using＜input type＝＂password＂＞ ..... 240
7．2．3 A Multiline Text Input Field Using＜textarea＞ ..... 241
7．2．4 A Selection List or Dropdown List Using＜select〉 ..... 242
7．2．5 Creating a Group of Radio Buttons Using＜input type＝＂radio＂＞ ..... 244
7．2．6 Adding a Text Label Using＜label＞ ..... 245
7．2．7 Using Checkboxes via＜input type＝＂checkbox＂＞ ..... 245
7．2．8 Using Fields for File Uploads via＜input type＝＂file＂＞ ..... 246
7．2．9 Overview of Various Buttons ..... 247
7．2．10 Using a Hidden Input Field via＜input type＝＂hidden＂＞ ..... 248
7．2．11 Writing Form Fields outside of 〈form＞．．．＜／form＞ ..... 248
7．2．12 Multiple Submit Buttons for Different URLs ..... 249
7．3 Special Types of Input Fields ..... 250
7．3．1 An Input Field for Colors Using＜input type＝＂color＂＞ ..... 251
7．3．2 An Input Field for a Date Using＜input type＝＂date＂＞ ..... 252
7．3．3 An Input Field for a Time Using＜input type＝＂time＂＞ ..... 252
7．3．4 Input Fields for Date and Time ..... 253
7．3．5 Input Fields for the Month and the Week ..... 254
7．3．6 An Input Field for Searches Using＜input type＝＂search＂＞ ..... 254
7．3．7 An Input Field for Email Addresses Using＜input type＝＂email＂〉 ..... 255
7．3．8 An Input Field for a URL Using＜input type＝＂url＂＞ ..... 255
7．3．9 An Input Field for Phone Numbers Using＜input type＝＂tel＂＞ ..... 256
7．3．10 An Input Field for Numbers Using＜input type＝＂number＂＞ ..... 256
7．3．11 An Input Field for Numbers of a Certain Range ..... 256
7．3．12 Outputting Values and Calculations Using＜output＞ ..... 256
7．4 The HTML Attributes for Input Fields ..... 257
7．4．1 Setting the Input Focus Using the HTML Attribute＂autofocus＂ ..... 258
7．4．2（De）activating Autocompletion Using the＂autocomplete＂ Attribute ..... 258
7．4．3 A List of Suggestions for Using the HTML Attribute＂list＂and ＜datalist＞ ..... 259
7．4．4 Specifying Minimum and Maximum Values and the Step Siz ..... 259
7．4．5 Selecting or Entering Multiple Values Using＂multiple＂ ..... 260
7．4．6 Regular Expressions for Input Fields Using＂pattern＂ ..... 260
7．4．7 A Placeholder for an Input Field Using＂placeholder＂ ..... 260
7．4．8 Defining an Input as Required Using the＂required＂Attribute ..... 261
7．4．9 Controlling Error Messages for Input Fields ..... 261
7．5 Other Useful Helpers for Input Fields ..... 263
7．5．1 Disabling Form Elements Using the HTML Attribute＂disabled＂ ..... 264
7．5．2 Permitting Read－Only for Input Fields Using the＂readonly Attribute ..... 265
7．5．3 Useful Keyboard Shortcuts and Tab Sequence for Input Fields ..... 265
7．5．4 Grouping Form Elements Using＜fieldset＞and＜legend＞ ..... 266
7．5．5 Progress Display via＜progress＞ ..... 267
7．5．6 Visualizing Values Using＜meter＞ ..... 268
7．6 Sending Form Data Using PHP ..... 268
7．6．1 Transferring the Data from the Web Browser for Further Processing ..... 269
7．6．2 The＂POST＂Method ..... 271
7．6．3 The＂GET＂Method ..... 271
7．6．4 Processing the Data Using a PHP Script ..... 272
7．7 Interactive HTML Elements ..... 275
7．7．1 Expanding／Collapsing Content Using＜details＞and＜summary＞ ..... 275
7．7．2 A Dialog Box via＜dialog＞ ..... 276
7．8 Summary ..... 277
8 Introduction to Cascading Style Sheets ..... 279
8．1 The Story of CSS ..... 280
8．2 The Basic Principle of Using CSS ..... 281
8．2．1 Structure of a CSS Rule ..... 283
8．2．2 Declaring a Selector ..... 283
8．2．3 Using Comments for CSS Code ..... 284
8．2．4 A Few Notes on Formatting CSS Code ..... 285
8．3 Integrating CSS into HTML ..... 285
8．3．1 Style Statements Directly in the HTML Tag Using the HTML Attribute＂style＂ ..... 286
8.3.2 Style Statements in the Document Head Using theHTML Element <style>287
8.3.3 Integrating Style Statements from an External CSS File Using <link> ..... 288
8.3.4 Combining CSS Rules in the Head Section and in External CSS Files... ..... 289
8.3.5 Recommendation: You Should Separate HTML and CSS ..... 291
8.3.6 Testing Alternate Stylesheets during Development ..... 291
8.3.7 Integrating Style Statements from an External CSS File Using "@import" ..... 293
8.3.8 Media-Specific Stylesheets for Specific Output Devices ..... 293
8.3.9 Media-Specific Stylesheets with CSS ..... 295
8.4 Analyzing CSS in the Web Browser ..... 295
8.5 Summary ..... 296
9 The Selectors of CSS ..... 297
9.1 The Simple Selectors of CSS ..... 298
9.1.1 Addressing HTML Elements Using the Type Selector ..... 299
9.1.2 Addressing HTML Elements Using a Specific Class or ID ..... 308
9.1.3 Universal Selector: Addressing All Elements in a Document ..... 308
9.1.4 Addressing Elements Based on Attributes Using the310
9.1.5 An Attribute Selector for Attributes with a Specific Value ..... 312
9.1.6 Attribute Selector for Attributes with a Specific Partial Value ..... 315
9.1.7 CSS Pseudo-Classes: The Selectors for Specific Features ..... 318
9.1.8 The Convenient Structural Pseudo-Classes in CSS ..... 322
9.19 Other Useful Pseudo-Classes ..... 329
9.1.10 Pseudo-Elements: The Selectors for Nonexistent Elements ..... 330
9.2 Combinators: Concatenating the Selectors ..... 332
9.2.1 The Descendant Combinator (E1 E2) ..... 334
9.2.2 The Child Combinator (E1 > E2) ..... 335
9.2.3 The Adjacent Sibling Combinator (E1 + E2) ..... 337
9.2.4 The General Sibling Combinator (E1~E2) ..... 338
9.3 Recommendation: How to Use Efficient and Simple CSS ..... 340
9.3.1 How to Write Well Performing CS ..... 340
9.3.2 Recommendation: Keep the CSS Code as Simple as Possible ..... 342
9.4 Summary ..... 343
10 Inheritance and Cascading ..... 345
10.1 The Principle of Inheritance in CSS ..... 345
10.1.1 Be Cautious When Using Relative Properties ..... 349
10.1.2 Not Everything Gets Inherited ..... 350
0.1.3 Enforcing Inheritance Using "inherit ..... 350
10.1.4 Restoring the Default Value of a CSS Feature ("initial") ..... 352
10.1.5 Forcing Inheritance or Restoring a Value ("unset") ..... 352
10.1.6 Forcing Inheritance or Restoring Values for All Properties ..... 353
10.2 Understanding the Control System for Cascading ..... 354
10.2.1 The Origin of a Stylesheet ..... 354
10.2.2 Increasing the Priority of a CSS Feature Using "!important" ..... 355
10.2.3 Sorting by Importance and Origin ..... 356
10.2.4 Sorting by Weighting the Selectors (Specificity) ..... 357
10.2.5 Summary of the Cascading Rules System ..... 361
10.2.6 Analyzing the Cascading in the Browser ..... 362
10.3 Related Topic: Passing Values to CSS Features ..... 363
10.3.1 Different Units of Measurement in CSS ..... 363
10.3.2 Character Strings and Keywords as Values for CSS Features ..... 365
10.3.3 Many Ways of Using a Color in CSS ..... 366
10.3.4 Angular Dimensions in CSS ..... 372
10.3.5 Passing Values via Short Notation to a CSS Feature ..... 373
10.4 Summary ..... 374
11 The Box Model of CSS ..... 375
111 Classic Box Model of CSS ..... 376
11.1.1 Specifying the Content Area Using "width" and "height" ..... 376
11.1.2 Specifying the Inner Spacing Using "padding ..... 378
11.1.3 Creating the Border Using "border" ..... 379
11.1.4 Setting Up the Outer Margin Using "margin" ..... 379
11.1.5 Collapsing Margins ..... 381
11.1.6 Determining the Total Width and Total Height of a Box ..... 385
11.2 Newer Alternate Box Model of CSS ..... 386
11.2.1 Using the "box-sizing" Box Model. ..... 388
11.2.2 Using the Alternate Box Model ..... 388
11.3 Analyzing the Box Model in the Browser ..... 392
11.4 Box Model for Inline Elements ..... 393
11.5 Designing Boxes ..... 393
11.5.1 Adding and Designing a Border Using the "border" Property ..... 393
11.5.2 Setting a Background Color Using "background-color" ..... 397
11.5.3 Using Background Images ..... 397
11.5.4 Making Boxes Transparent ..... 405
11.5.5 Adding a Gradient ..... 406
11.5.6 Adding a Shadow Using the "box-shadow" Feature ..... 409
11.5.7 Adding Round Corners Using the CSS Feature "border-radius" ..... 411
11.6 Related Topic: Web Browser Prefixes (CSS Vendor Prefixes) ..... 413
11.7 Summary ..... 416
12 CSS Positioning ..... 417
12.1 Positioning via CSS Feature "position" ..... 417
12.1.1 Normal Positioning ("position: static") ..... 418
12.1.2 Positioning Elements Using "top", "right", "bottom", and "left" ..... 420
12.1.3 Relative Positioning ("position: relative") ..... 421
12.1.4 Absolute Positioning ("position: absolute") ..... 422
12.1.5 Fixed Positioning ("position: fixed") ..... 426
12.1.6 Sticky Positioning ("position: sticky") ..... 429
12.2 Controlling Stacking Using "z-index" ..... 431
12.3 Floating Boxes for Positioning via "float" ..... 434
12.3.1 Terminating the Float ..... 438
12.3.2 Combining Floats into One Entity ..... 440
12.4 Flexible Boxes of CS ..... 443
12.4.1 Aligning the Flexbox ..... 443
12.4.2 Setting the Flexibility of the Flexbox ..... 451
12.4.3 Determining the Order of the Boxes ..... 454
12.5 Summary ..... 454
13 Creating Responsive Layouts with CSS457
13.1 Basic Theoretical Knowledge of Responsive Web Design ..... 457
13.1.1 Using Specific Media Types ..... 458
3.1.2 Media Queries for Media Features ..... 461
13.1.3 Integrating and Applying Media Queries for Media Features ..... 461
13.1.4 Basic Structure of a Media Feature Query ..... 462
13.1.5 Which Media Features Can Be Queried? ..... 464
13.1.6 Crucially Important: The Viewport for Mobile Devices ..... 465
13.1.7 Use "em" Instead of Pixels for a Layout Break in Media Queries ..... 469
13.1.8 Layout Breaks (Breakpoints) ..... 471
13.1.9 No More Math Games Thanks to "box-sizing: border-box;" ..... 472
13.1.10 What Happens to Web Browsers That Don't Understand Media Queries? ..... 472
13.2 Let's Create a Simple Responsive Layout ..... 472
13.2.1 Let's Create the Basic Framework Using HTML ..... 473
3.2.2 Setting General CSS Features ..... 474
13.2.3 What Should I Use as a Basic Version without Media Queries Mobile First? ..... 475
3.2.4 Setting the Layout Break (Breakpoint) ..... 480
13.2.5 Adding More Layout Breaks ..... 482
13.2.6 Customizing the Main Content ..... 487
13.3 Even More Flexible Elements ..... 489
3.3.1 Use Relative Font Sizes instead of Pixels ..... 489
13.3.2 Making Images Responsive ..... 489
13.3.3 Flexible Images in Maximum Possible Width ..... 493
13.3.4 Hiding Images Entirely ..... 495
13.3.5 Loading the Right Image for the Screen Width: <picture ..... 496
13.3.6 Using Area-Covering Images ..... 498
13.4 CSS Grid Layou ..... 501
13.4.1 Creating a Grid for the Content ..... 501
13.4.2 Placing Elements in the Grid ..... 504
13.4.3 Layout Changes Made Easy ..... 510
13.4.4 Spacing between Grid Lines ..... 511
13.4.5 Checking the Grid in the Web Browser ..... 512
13.5 Changing the Behavior of HTML Elements Using "display" ..... 513
13.5.1 "display: block", "display: inline", and "display: inline-block" ..... 513
13.5.2 Hiding Elements Using "display:none" ..... 515
13.5.3 Further Values for "display" ..... 516
13.6 Calculations Using CSS and the "calc()" Function ..... 516
13.7 Summary ..... 519
14 Styling with CSS ..... 521
14.1 Designing Texts with CSS ..... 521
14.1.1 Selecting Fonts via "font-family"
14.1.1 Selecting Fonts via "font-family" ..... 522 ..... 522
14.1.2 Providing Fonts via Web Fonts: "@font-face" ..... 526
14.1.3 Using Icons via Icon Fonts ..... 532
14.1.4 Setting the Font Size Using "font-size" ..... 536
14.1.5 Italic and Bold Fonts via "font-style" and "font-weight" ..... 543
14.1.6 Creating Small Caps Using "font-variant" ..... 544
14.1.7 Defining Line Spacing via "line-height" ..... 545
14.1.8 A Short Notation for Font Formatting Using "font" ..... 546
14.1.9 Specifying Letter and Word Spacing via "letter-spacing" and "word-spacing" ..... 547
4.1.10 Setting the Text Alignment Using "text-align ..... 548
14.1.11 Setting the Vertical Alignment via "vertical-align" ..... 550
14.1.12 Indenting Text Using "text-indent" ..... 551
14.1.13 Underlining Text and Striking Text Through Using text-decoration" ..... 552
14.1.14 Uppercase and Lowercase Text via "text-transform" ..... 553
14.1.15 Adding Shadow to Text via "text-shadow" ..... 554
14.1.16 Splitting Text into Multiple Columns Using "column-count" ..... 555
14.2 Designing Lists with CSS ..... 557
14.2.1 Customizing Bullet Points Using "list-style-type" ..... 557
14.2.2 Using Images as Bullets via "list-style-image" ..... 559
14.2.3 Positioning Bulleted Lists via "list-style-position ..... 560
14.2.4 Short Notation "list-style" for Designing List ..... 560
14.2.5 Creating Navigation and Menus via Lists ..... 561
14.3 Designing Appealing Tables with CSS ..... 566
14.3.1 Creating Fixed-Width Tables ..... 566
14.3.2 General Recommendation: Designing Appealing Tables with CSS ..... 567
14.3.3 Collapsing Borders for Table Cells Using "border-collapse" ..... 568
14.3.4 Setting the Spacing between Cells via "border-spacing" ..... 569
14.3.5 Displaying Empty Table Cells Using "empty-cells" ..... 570
14.3.6 Positioning Table Captions via "caption-side" ..... 571
14.4 Adjusting Images and Graphics Using "width" and "height" ..... 571
14.5 Transforming Elements with CSS ..... 574
14.5.1 Scaling HTML Elements via "transform: scale()" ..... 575
14.5.2 Rotating HTML Elements Using "transform: rotate()" ..... 576
14.5.3 Skewing HTML Elements Using "transform: skew()" ..... 577
14.5.4 Moving HTML Elements Using "transform: translate()" ..... 577
14.5.5 Combining Different Transformations ..... 578
14.5.6 Other HTML Elements ..... 579
14.6 Creating Transitions with CSS ..... 580
14.7 Styling HTML Forms with CSS ..... 581
14.7.1 Neatly Structuring an HTML Form ..... 582
14.7.2 Aligning Form Elements with CSS ..... 584
14.7.3 Designing Form Elements with CSS ..... 587
14.8 Summary ..... 590
15 Testing and Organizing ..... 591
15.1 Web Browser Tests: What's Possible? ..... 591
15.1.1 Validating HTML and CSS ..... 592
15.1.2 Which Browsers Are Visitors Currently Using? ..... 592
15.1.3 CSS Web Browser Test ..... 593
15.1.4 HTML5 Web Browser Tes ..... 594
15.1.5 Can I Use That? ..... 595
15.1.6 Feature Query Using the "@supports" Rule ..... 596
15.2 Viewing Websites in Different Sizes ..... 596
15.3 Setting Up a Central Stylesheet ..... 598
15.3.1 Combining Everything Back into One File to Shorten the Load Time .. ..... 600
15.4 CSS Reset or Normalization? ..... 600
15.4.1 Built-In Style Presets of the Web Browser and CSS Reset ..... 600
15.4.2 Normalization: The Alternative to CSS Reset ..... 602
15.5 Summary ..... 603
16 The CSS Preprocessor Sass and SCSS ..... 605
16.1 Sass or SCSS Syntax ..... 605
16.2 From Sass/SCSS to CSS ..... 606
16.3 Installing and Setting Up Sass ..... 607
6.3.1 Online CSS Preprocessor without Installation ..... 607
16.3.2 Setting Up Sass Using Visual Studio Code ..... 608
16.3.3 Installing Sass for the Command Line ..... 610
16.4 Using Variables with Sass ..... 611
16.5 Nesting with Sass ..... 613
16.6 Mixins ("@mixin", "@include") ..... 615
16.7 Extend ("@extend") ..... 618
16.8 Media Queries and "@content" ..... 621
16.9 Operators ..... 624
16.10 Adjusting Colors and Brightness ..... 625
16.11 Sass Control Structures ..... 628
16.12 Functions "@function" ..... 632
16.13 "@import" ..... 633
16.14 Comments ..... 634
16.15 Summary ..... 635
17 A Brief Introduction to JavaScript ..... 637
17.1 JavaScript in Web Development ..... 638
17.2 Writing and Executing JavaScript Programs ..... 640
17.2.1 Integrating a JavaScript File in an HTML File ..... 641
17.2.2 Writing JavaScript within HTML ..... 643
17.2.3 Position of JavaScript and Its Execution in the HTML Document ..... 644
17.2.4 Attributes for Manipulating the Load Behavior of JavaScript ("async", "defer") ..... 645
17.2.5 The <noscript> Element for No JavaScript ..... 645
17.3 JavaScript Output ..... 646
17.3.1 Standard Dialogs (and Input Dialog) ..... 646
17.3.2 Outputting to the Console ..... 647
17.3.3 Outputting to the Website ..... 649
17.3.4 Running JavaScript without a Web Browser ..... 651
17.3.5 Annotating JavaScript Code with Comments . ..... 652
17.4 Using Variables in JavaScrip ..... 652
17.4.1 Defining Constants ..... 655
17.4.2 Strict Mode Using ""use strict"" ..... 656
17.5 Overview of JavaScript Data Types ..... 657
17.5.1 Number Data Type (Numbers) ..... 657
17.5.2 String Data Types (Strings) ..... 658
17.5.3 Template Strings ..... 660
17.5.4 Boolean Data Type ..... 660
17.5.5 Undefined and Null Data Types ..... 661
17.5.6 Objects ..... 662
17.5.7 Converting Data Types ..... 662
17.6 Arithmetic Operators for Calculation Tasks in JavaScript ..... 663
17.7 Conditional Statements in JavaScript ..... 665
17.7.1 "true" or "false": Boolean Truth Value ..... 666
17.7.2 Using the Various Comparison Operators in JavaScript ..... 667
17.7.3 Using the "if" Branch ..... 668
17.7.4 Using the Selection Operator ..... 669
17.7.5 Logical Operators ..... 669
17.7.6 Multiple Branching via "switch" ..... 670
17.8 Multiple Repetitions of Program Statements via Loops ..... 672
17.8.1 Increment and Decrement Operators ..... 672
17.8.2 The Header-Controlled "for" Loop ..... 673
17.8.3 The Header-Controlled "while" Loop ..... 674
17.8.4 The Footer-Controlled "do-while" Loop ..... 674
17.8.5 Ending the Statement Block Using "break" ..... 675
17.8.6 Jumping to the Start of the Loop via "continue" ..... 675
17.9 Summary ..... 676
18 Arrays, Functions, and Objects in JavaScript ..... 677
18.1 Functions in JavaScript ..... 677
8.1.1 Different Ways to Define a Function in JavaScript ..... 678
18.1.2 Calling Functions and Function Parameters ..... 680
18.1.3 Return Value of a Function ..... 683
18.1.4 The Scope of Variables in a Function ..... 683
18.1.5 Defining Functions in Short Notation (Arrow Functions) ..... 686
18.1.6 Using a Function in a Web Page ..... 687
18.2 Arrays ..... 689
18.2.1 Accessing the Individual Elements in the Array ..... 690
18.2.2 Multidimensional Arrays ..... 691
18.2.3 Adding or Removing New Elements in an Array ..... 692
18.2.4 Sorting Arrays ..... 697
18.2.5 Searching within Arrays ..... 698
18.2.6 Additional Methods for Arrays ..... 699
18.3 Strings and Regular Expressions ..... 700
18.3.1 Useful Functions for Strings ..... 700
18.3.2 Applying Regular Expressions to Strings ..... 701
18.4 Object-Oriented Programming in JavaScrip ..... 702
18.4.1 What Exactly Are Objects? ..... 702
18.4.2 Creating Objects via Constructor Functions ..... 703
18.4.3 Creating Objects via the Class Syntax ..... 704
18.4.4 Accessing the Object Properties and Methods: Setters and Getters ..... 705
18.4.5 The Keyword "this" ..... 708
18.5 Other Global Objects ..... 709
18.5.1 The Top Object "Object" ..... 709
18.5.2 Objects for the Primitive Data Types: Number, String, and Boolean . ..... 709
18.5.3 "Function" Object ..... 711
18.5.4 "Date" Object ..... 711
18.5.5 "Math" Object ..... 711
18.5.6 "Map" Object ..... 712
18.5.7 "Set" Object ..... 712
18.6 Summary ..... 713
19 Changing Web Pages Dynamically ..... 715
19.1 Introduction to the DOM of an HTML Document ..... 715
19.2 The "document" Object ..... 717
19.3 DOM Programming Interface ..... 717
19.4 Accessing Elements in the DOM ..... 718
19.4.1 Finding an HTML Element with a Specific "id" Attribute ..... 719
19.4.2 Finding HTML Elements with a Specific Tag Name ..... 720
19.4.3 Finding HTML Elements with a Specific "class" Attribute ..... 723
19.4.4 Finding HTML Elements with a Specific "name" Attribute ..... 724
19.4.5 Using "querySelector()" and "querySelectorAll()" ..... 725
19.4.6 Other Object and Property Collections ..... 727
19.5 Changing an HTML Element, an Attribute, or the Style ..... 730
19.5.1 Changing the Content of HTML Elements Using "innerHTML" ..... 730
19.5.2 Changing the Value of an HTML Attribute ..... 732
19.5.3 Changing the Style (CSS) of an HTML Element ..... 733
19.6 Responding to JavaScript Events ..... 735
19.7 Handling the Events Using the Event Handler ..... 736
19.7.1 Setting Up an Event Handler as an HTML Attribute in the HTML Element ..... 737
19.7.2 Setting Up Event Handlers as a Property of an Object ..... 737
19.7.3 Setting Up an Event Handler via "addEventlistener()" ..... 738
19.8 Overview of Common JavaScript Events ..... 740
19.8.1 The JavaScript Events of the UI (Window Events) ..... 740
19.8.2 JavaScript Events That Can Occur in Connection with the Mouse ..... 742
19.8.3 JavaScript Events for Devices with a Touchscreen ..... 744
19.8.4 JavaScript Events That Occur in Connection with the Keyboard ..... 744
19.8.5 JavaScript Events for HTML Forms ..... 745
19.8.6 JavaScript Events for the Web APIs ..... 745
19.9 More Information about Events with the "event" Object ..... 745
19.10 Suppressing the Default Action of Event ..... 748
19.11 The Event Flow (Event Propagation) ..... 749
19.11.1 More about the Bubbling Phase ..... 750
19.11.2 Canceling Bubbling via the "stopPropagation()" Method ..... 751
19.11.3 Intervening in the Event Flow during the Capturing Phase ..... 752
19.11.4 Additional Information on the Capturing and Bubbling Phases ..... 753
19.12 Adding, Changing, and Removing HTML Elements ..... 754
19.12.1 Creating and Adding a New HTML Element and Content ..... 755
19.12.2 Targeting HTML Elements Even More Exactly in the DOM Tree ..... 756
19.12.3 Adding a New HTML Element Even More Targeted to the DOM Tree

\(\qquad\) ..... 760
19.12.4 Deleting an Existing HTML Element from the DOM Tree ..... 762
19.12.5 Replacing an HTML Element in the DOM Tree with Another One ....... ..... 763
19.12.6 Cloning a Node or Entire Fragments of the DOM Tree ..... 764
19.12.7 Different Methods to Manipulate the HTML Attributes ..... 765
19.12.8 The <template> HTML Tag ..... 768
19.13 HTML Forms and JavaScript ..... 770
19.13.1 Reading Text Input Fields with JavaScript ..... 771
19.13.2 Reading Selection Lists with JavaScript ..... 772
9.13.3 Reading Radio Buttons and Checkboxes with JavaScript ..... 773
19.13.4 Intercepting Buttons with JavaScript ..... 775
19.13.5 Controlling the Progress Indicator <progress> with JavaScript ..... 776
19.14 Summary ..... 777
20 An Introduction to Ajax ..... 779
20.1 An Introduction to Ajax Programming ..... 779
20.1.1 A Simple Ajax Example in Execution ..... 781
20.1.2 Creating the "XMLHttpRequest" Object ..... 783
20.1.3 Making a Request to the Server ..... 783
20.1.4 Sending Data ..... 784
20.1.5 Determining the Status of the "XMLHttpRequest" Object ..... 785
20.1.6 Processing the Response from the Server ..... 787
20.1.7 The Ajax Example during Execution797
The Author ..... 799Index .801
