**SCOPE**

A 30” Crude Oil Pipeline had suffered a through-wall defect previously. A clamp was the initial preferred method of repair, however this had failed and was actively leaking. ICR were tasked to provide a solution to repair the leaking clamp whilst the line was still live and the leak still active.

**SOLUTION**

ICR’s Technowrap™ 2K fibreglass cloth with HA resins were used. Firstly a sump was formed, with a large threaded nut placed into the centre of the cured composite cloth, and manoeuvred into place in the underside of the pipework. This was held in place with ratchet straps. Once cured, layers were applied around the threaded nut with the leak actively exiting at this point. Once the repair around the nut was fully cured, a bolt was screwed into the thread and the required number of layers applied over the bolted area of the sump to secure and seal.

**RESULTS & BENEFITS**

- The repair was applied live, resulting in no downtime and zero impact to production and operations.
Clamp requiring profiling using Technoseal FP

Composite sump formed at the top of pipe ready to be manoeuvred to the underside of the pipework

Sump moved to the 6 o’clock position on the underside of the pipework

Sump held in place using ratchet straps and either side secured to the pipe with a composite repair

Once both sides of the sump had cured and held in place, layers were applied over the middle

Layers being built up over the full length of the repair
TECHNOWRAP™ 2K HA
30” CRUDE OIL LEAKING CLAMP

View of threaded nut secured in the layers

All layers applied and cured surrounding the nut

Threaded bolt fitted to nut to secure diesel in the sump. Cloth applied over the top of the bolt.

Completed repair encapsulating the clamp and leaking bolt hole.
