LIST OF TABLES:

Table S-1. List of internal standards used for quantification and matrix correction factor calculations.	2
Table S-2. Summary of the higher collision dissociation (HCD) energies used for nontarget masses on the inclusion list for MS/MS measurement.	5
Table S-3. Settings used for peak picking in the enviPick software.	6
Table S-4. Settings used for feature profiling in enviMass software.	6
Table S-5. Results from targeted screening of the validation pairs, including PC1 loading in principal component analysis (PCA), and additional statistical tools applied.	7
Table S-6. Summary of the validation pairs used for the PCA and difference analysis in the nontarget workflow.	11
Table S-7. Biotransformations from negative mode data included in the difference analysis, with mass difference and atomic loss or gain.	17
Table S-8. Summary of the MS/MS similarity score calculations with the validation pairs.	22

LIST OF FIGURES:

Figure S-1. Ratio of areas of each internal standard for matrix factor correction, measured in positive ionization.	9
Figure S-2a. PC1 vs. PC2 scores plot for all peaks in validation samples, measured in positive ionization.	10
Figure S-2b. PC1 vs. PC2 loading plot for all peaks in validation samples, measured in positive ionization.	10
Figure S-3a. Distribution of detected features (n=14268) in the influent samples in positive electrospray.	12
Figure S-3b. Distribution of detected features (n=5964) in the effluent samples in positive electrospray.	12
Figure S-4a. Distribution of detected features (n=16483) in the influent samples in negative electrospray.	13
Figure S-4b. Distribution of detected features (n=1172) in the effluent samples in negative electrospray.	13
Figure S-5a. PC1 vs. PC2 scores plot for all peaks in the unspiked samples, measured in positive ionization mode.	14
Figure S-5b. PC1 vs. PC2 loading plot for all peaks in the unspiked samples, measured in positive ionization mode.	14
Figure S-6. PC1 vs. PC5 scores plot for all peaks in the unspiked samples, measured in positive ionization mode.	15
Figure S-7a. PC1 vs. PC2 scores plot for all peaks in the unspiked samples, measured in negative ionization mode.	16
Figure S-7b. PC1 vs. PC2 loading plot for all peaks in the unspiked samples, measured in negative ionization mode.	16
Figure S-8. Comparison of the different transformation types detected in the linkage analysis in both positive (in blue) and negative (in red) ionization modes, in the percentage of the total number of links detected.	18
Figure S-9. Example of the trend visualization for selecting links for targeted MS/MS measurements.	19
Figure S-10. Example of head to tail plot for visual comparison of the MS/MS similarity of each link.	19
Figure S-11. Isotopic pattern of a parent compound identified to likely be a polypeptide.	20
Figure S-12. Isotopic pattern of a transformation product identified as likely to be resulting from a polypeptide.	20
Figure S-13. Proposed structural candidates from MetFrag for possibly ethoxylated parent compound structure.	21
Figure S-14. Example of interferences in a nontarget peak.	21
Figure S-15. MS/MS of the parent and transformation product of a hydrogenation link with highest MS/MS similarity score.	21

Table S-1. List of internal standards used for quantification and matrix correction factor calculations.

Internal Standard Name	Formula	Monoisotopic mass	Retention time	[M+H] ⁺

DATA-DEPENDENT MS/MS MEASUREMENTS

For data-dependent MS/MS measurements a scan resolution of 17,500 and scan range of m/z 200 to 2000 were used. A “top 5, pick others” experiment was executed, where first masses on the inclusion list were selected, then the other (*i.e.*, most intense) masses were selected and fragmented. Five cycles of MS/MS measurement were included for each cycle of full scan MS. A dynamic exclusion window of 8 seconds was set, meaning that once triggered, a mass would be placed on a temporary exclusion list for 8 seconds to ensure that one mass would not dominate all MS/MS scans. The automatic gain control (AGC) target was set at 200,000 and maximum injection time was 100 milliseconds. For fragmentation, normalized collision energies (NCE) were used for the nontarget peaks on the inclusion list. NCE was determined based on the mass of the nontarget compound. See Table S-2 below for the distribution.

Table S-2. Summary of the higher collision dissociation (HCD) energies used for nontarget masses on the inclusion list for MS/MS measurement.

m/z Range	HCD energy (NCE)
<124	90
124 – 148	85
148 – 172	80
172 – 197	75
197 – 224	70
224 – 251	65
251 – 277	60
277 – 304	55
304 – 329	50
329 – 355	45
355 – 380	40
380 – 407	35
407 – 434	30
434 – 460	25
460 – 478	20
>478	15

Table S-5. Results from targeted screening of the validation pairs, including PC1 loading in principal component analysis (PCA), and additional statistical tools applied. Fold change is ratio of mean intensity of influent samples to mean intensity of effluent samples. Wilcox U-test and indicator species analysis were calculated using the intensities of the features in each sample. “Related to” column is the majority vote of the evidence from each of these tools and to which group (if any) each compound was associated with based on the evidence. The reason for non-association is provided in last column.

Compound	CAS number	PCA PC1 loading	PLS-DA PC1 loading	Fold change	Wilcox p-value	Influent indicator	Effluent indicator	Related to	Reasons
Atrazine	1912-24-9	-0.159	-0.162	16	9.77E-04	F	F	None	Indicator analysis

Figure S-1. Ratio of areas of each internal standard for matrix factor correction, measured in positive ionization. While a slight downward trend could be observed, the correlation was not strong enough to justify a blanket matrix factor correction of all nontarget peaks. The outlier at 4.78 minutes is the compound Ritaline.

Figure S-2a. PC1 vs. PC2 scores plot for all peaks in validation samples, measured in positive ionization. Here the first two PC are displayed, with PC1 on the x-axis and PC2 along the y-axis. Both of the major variances in the data are capture here; for example influent and effluent sample types are well explained by PC1, while composites are differentiated in PC2.

Figure S-2b. PC1 vs. PC2 loading plot for all peaks in validation samples, measured in positive ionization mode. Here the first two PC are displayed, with PC1 on the x-axis and PC2 along the y-axis. Each circle represents a unique m/z and RT feature detected during the peak picking and feature building. Classification of the peaks was done by comparing the feature loading to the sample scores plot.

Table S-6. Summary of the validation pairs used for the PCA and difference analysis in the nontarget workflow. Parent and the corresponding transformation product are shown; some parent compounds are related to multiple transformation products. The biotransformation that occurs is also indicated, as well as the compound class of the parent compound. The last column summarizes the result of the workflow for each pair, with a “yes” if the two compounds were linked together or a “no” and the reason when the match was not found.

	Parent compound	Compound class	Transformation	Transformation Product	Found when workflow applied to spiked samples?
1	Atrazine	Herbicide	deethylation	Desethylatrazine	Yes
2			desisopropyl	Desisopropylatrazine	Yes
3	Diuron	Herbicide	ethene loss	Diuron-desdimethyl	Yes
4			demethylation	Diuron-desmonomethyl (DCPMU)	Yes
5	Ethofumesate	Herbicide	deethylation	Ethofumesate-2-keto	Yes
6	Isoproturon	algicide, herbicide	ethene loss	Isoproturon-didemethyl	Yes
7			demethylation	Isoproturon-monodemethyl	Yes
8	Metamitron	Herbicide	amino loss	Metamitron-Desamino	Yes
9	Metribuzin	Herbicide	amino loss	Metribuzin-Desamino	Yes
10	Terbutylazine	Herbicide	hydrolysis	Terbutylazine-2-hydroxy	No, TP in influent
11	Oseltamivir	pharmaceutical	ethene loss	Oseltamivir-carboxylate	Yes
12	Ranitidine	pharmaceutical	oxidation	Ranitidine-S-oxide	No, parent is not well degraded so not associated with either influent or effluent
13			oxidation	Ranitidine-N-oxide	No, parent is not well degraded so not associated with either influent or effluent
14	Sulfadiazine	pharmaceutical	acetylation	N4-Acetyl-Sulfadiazine	Yes
15	Sulfadimethoxine	pharmaceutical	acetylation	N4-Acetyl-Sulfadimethoxine	Yes
16	Sulfamethazine	pharmaceutical	acetylation	N4-Acetyl-Sulfamethazine	Yes
17	Sulfathiazole	pharmaceutical	acetylation	N4-Acetyl-Sulfathiazole	No, poor peak shapes so not selected by the peak picker.

Figure S-3a. Distribution of detected features (n=14268) in the influent samples in positive electrospray. Each circle represents the mean m/z and retention time in influent samples of this feature. Color of the circle indicates the mean log₁₀ intensity of the feature in all influent samples.

Figure S-3b. Distribution of detected features (n=5964) in the effluent samples in positive electrospray. Each circle represents the mean m/z and retention time in effluent samples of this feature. Color of the circle indicates the mean log₁₀ intensity of the feature in all effluent samples. In comparison to Figure S-3a, a large decrease of features can be observed, as well as a general trend towards lower retention times, lower masses, and lower intensities.

Figure S-4a. Distribution of detected features ($n=16483$) in the influent samples in negative electrospray. Each circle represents the mean m/z and retention time in influent samples of this feature. Color of the circle indicates the mean \log_{10} intensity of the feature in all influent samples.

Figure S-4b. Distribution of detected features ($n=1172$) in the effluent samples in negative electrospray. Each circle represents the mean m/z and retention time in effluent samples of this feature. Color of the circle indicates the mean \log_{10} intensity of the feature in all effluent samples. In comparison to Figure S-3a, a large decrease of features can be observed, as well as a general trend towards lower retention times, lower masses, and lower intensities.

Figure S-5a. PC1 vs. PC2 scores plot for all peaks in the unspiked samples, measured in positive ionization mode. The first two PC are displayed, with PC1 along the x-axis and PC2 on the y-axis. Both of the major variances in the data are captured here; for example influent and effluent sample types are well separated by PC1, while composites are differentiated in PC2. It appears that variance in the influent samples is greater than that in the effluent samples, which are here not separated at all in the 2nd dimension. A quality control effluent sample without spiked internal standards is displayed in orange and was correctly grouped with the other effluent samples.

Figure S-5b. PC1 vs. PC2 loading plot for all peaks in the unspiked samples, measured in positive ionization mode. The first two PC are displayed, with PC1 along the x-axis and PC2 on the y-axis. Each circle represents a unique m/z and RT feature detected during the peak picking and feature building. Classification of the peaks was done by comparing the feature loading to the sample scores plot in Figure S-5a.

Figure S-6. PC1 vs. PC5 scores plot for all peaks in the unspiked samples, measured in positive ionization mode. Here the first and fifth PCs are displayed, with PC1 along the x-axis and PC5 on the y-axis. The first PC shows the separation of the influent and effluent sample types, while the fifth PC appears to capture the variance resulting from the different effluent composites. But compared to variance contributed to the influent composites (11%, Figure S-5a), this effect appears to be quite minor. A quality control effluent sample without spiked internal standards is displayed in orange and was correctly grouped with the other effluent samples.

Figure S-7a. PC1 vs. PC2 scores plot for all peaks in the unspiked samples, measured in negative ionization mode. The first two PC are displayed, with PC1 along the x-axis and PC2 on the y-axis. Both of the major variances in the data are captured here; for example influent and effluent sample types are well separated by PC1, while composites are differentiated in PC2. It appears that variance in the influent samples is greater than that in the effluent samples, which are here not separated at all in the 2nd dimension. A quality control effluent sample without spiked internal standards is displayed in orange and was correctly grouped with the other effluent samples. The patterns observed here were very similar to those found in analysis of the positive ionization data (Figure S-5a).

Figure S-7b. PC1 vs. PC2 loading plot for all peaks in the unspiked samples, measured in negative ionization mode. The first two PC are displayed, with PC1 along the x-axis and PC2 on the y-axis. Each circle represents a unique m/z and RT feature detected during the peak picking and feature building. Classification of the peaks was done by comparing the feature loading to the sample scores plot in Figure S-a.

SUMMARY OF NEGATIVE MODE DATA

Principal component analysis of the negative mode data showed very similar trends as were observed in the positive mode. Influent and effluent samples could be very well separated in the first PC. From this information, features could be attributed to either influent or effluent samples. Using the same PC1 cutoffs as in the positive mode (*i.e.*, +/- 0.005) 10,881 features were classified with the influent, while 4,080 features were classified with the effluent. These figures are similar to what was observed in the positive mode, where 9,758 influent peaks and 3,011 effluent peaks were selected.

Table S-7. Biotransformations included in the difference analysis, with mass difference and atomic loss or gain. Inventory of links and the detected isotopes calculated using the R ‘nontarget’ package. In some cases Cl/Br and S isotopes may be overlapping and therefore reported twice. Similarly N isotopes may also overlap with ¹³C isotopes. Data presented here is from nontarget analysis performed on negative ionization mode data.

Transformation		Atomic loss / gain	Mass difference (Da)	# of links before filter	# of links after filter	# of links with		
						Cl/Br isotopes	S isotopes	N isotopes
1	Hydroxylation	+ O	+15.9949	2242	1173	205	127	79

Comparison of Transformation Types detected in Positive and Negative Ionization Modes

Figure S-8. Comparison of the different transformation types detected in the linkage analysis in both positive (in blue) and negative (in red) ionization modes, in the percentage of the total number of links detected. Overall the distribution is very similar between the two ionization modes.

Figure S-9. Example of the trend visualization for selecting links for targeted MS/MS measurements. Extracted ion chromatograms (EICs) were plotted for both potential parent and potential TP masses of the top 300 most significant TP peaks. Here parent EICs are shown on the right, while TP EICs are shown on the left. The EICs are also colored according to the sample type, with influent samples in red and effluent samples in green. This example illustrates the ideal trend, with no parent peak detected in the effluent samples (*i.e.*, no green peak visible on the right) and only a very small TP peak detected in the influent samples (*i.e.*, small red peak on the left).

Figure S-10. Example of head to tail plot for visual comparison of the MS/MS similarity of each link. These plots are automatically generated as an output from the 'OrgMassSpecR' package. Parent compound MS/MS is plotted in blue in the upper half, while the MS/MS of the TP is shown in red in the lower half of the figure. The x-axis shows m/z values and the y-axis is relative intensities of the fragment peaks.

Linkage 3793 – MS Parent compound

Figure S-11. Isotopic pattern of a parent compound identified to likely be a polypeptide. The x-axis is the m/z values and the y-axis is the relative intensity of the peaks. Peaks are annotated with the measured exact mass. Mass difference of approximately 0.5 Da between the isotope peaks indicates a charge of +2 on this compound.

Linkage 3793 & 3794 – MS TP

Figure S-12. Isotopic pattern of a transformation product identified as likely to be resulting from a polypeptide. The x-axis is the m/z values and the y-axis is the relative intensity of the peaks. Peaks are annotated with the measured exact mass. Mass difference of approximately 0.5 Da between the isotope peaks indicates a charge of +2 on this compound.

Figure S-13. Proposed structural candidates from MetFrag for possibly ethoxylated parent compound structure

Figure S-14. Example of interferences in a nontarget peak. Exact mass of interest for the parent compound is 354.2486. A mass of equal/higher intensity is eluting simultaneously at 355.2377, which would obscure the $^{13}\text{C}/^{15}\text{N}$ isotope peaks. Additionally, the mass difference of these peaks is less than 1.0 Da, so both would be collected and fragmented for MS/MS, meaning that any fragments collected could not be attributed to a specific parent mass.

Linkage 694 – MS/MS Parent compound & TP

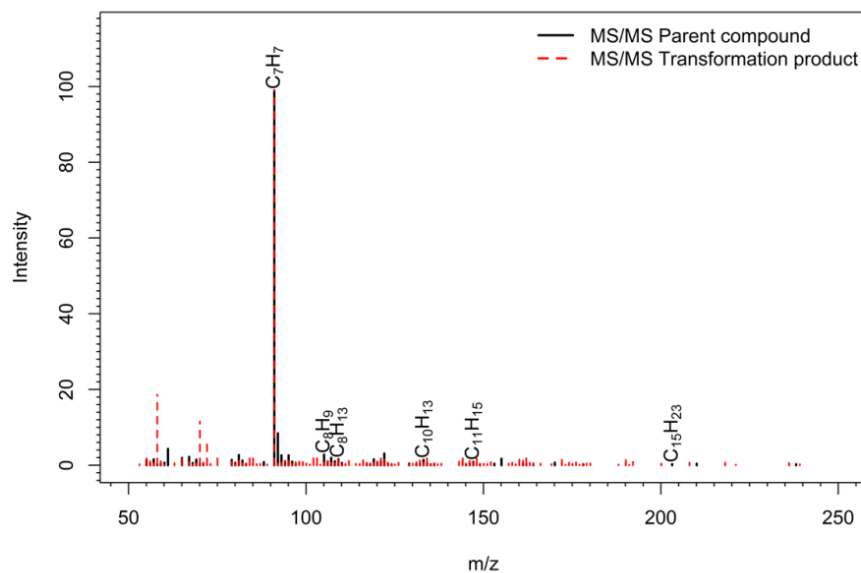

Figure S-15. MS/MS of the parent and transformation product of a hydrogenation link with highest MS/MS similarity score. The x-axis is the m/z values and the y-axis is the relative intensity of the fragments. Fragments from the parent compound are shown in black, while fragments in the transformation product are shown in red hatched. Fragments were annotated with formulas explained by GenForm.

Table S-8. Summary of the MS/MS similarity score calculations with the validation pairs. MS/MS spectra were collected for known parent/TP pairs in wastewater samples and in reference standards and then the similarity score was calculated with the ‘OrgMassSpecR’ package. Displayed here is the transformation product and the calculated score. “NoTP” indicates that no MS/MS spectra was collected for the transformation product in wastewater samples, while “NoPAR” means no spectra was collected for the parent compound in wastewater samples. “NA” indicates that no MS/MS spectra was collected for this reference standard.

	Transformation Product	Parent	Score in wastewater samples	Score in reference standards
