The FEI Tecnai Osiris TEM instrument was used for transmission electron microscopy and energy dispersive X-ray mapping. Calibration was performed using an automated procedure with a standardized Au-Pd grating. To ensure accuracy in the determination of lattice parameters, experimental samples were studied with the same imaging conditions as those for an Al calibration standard. Typically, the data images and/or diffraction pattern of an experimental samples are obtained followed by the study of the Al standard to the same electrical and magnetic conditions (i.e the same lens current or high voltage and positioning). Lattice parameters are assigned as per the below d-spacings for Al.

Following the assignment of the d-spacings, a calibration constant (K) is calculated using the formula \( K = S \times d \). \( K \) encompasses the wavelength of the electron beam, camera length and the associated variation in the crystallographic data, \( S \) represents the diameter of a diffraction ring in centimeters and \( d \) is the interplanar spacing in angstroms. The tolerance level for variation in the values for calibration constant for the first five lines is 1%. The imaging software is integrated with this calibration data to standardize the reciprocal readings of lattice spacing information acquired from FFT interpretations.

The Pt-loading of Pt\textsubscript{x}Au\textsubscript{y} bimetallic NPs produced from PS\textsubscript{n}-b-P4VP\textsubscript{m} diblock copolymer templates on ITO can be estimated from laser-ablation inductively coupled plasma mass spectroscopy (LA ICP-MS, see Table S4 for experimental parameters) analysis. Pt quantification by the LA ICP-MS was conducted by relating signal intensity for \textsuperscript{195}Pt to that of the \textsuperscript{118}Sn.
originating from the fully ablated ITO layer which is known to have constant composition and stoichiometry. Since the ITO substrate has a thickness of 100 nm and a composition of approximately 90 In_2O_3:10SnO_2, the \(^{118}\)Sn content of the substrate acts as an internal standard in the calculation. Table S5 reports the resulting estimates for Pt-loading per unit area for Pt\(_{x}\)Au\(_{y}\) bimetallic NPs produced from PS\(_{n}\)-b-P4VP\(_{m}\) diblock copolymer templates.

**Table S5.** Dimensions, Stoichiometry and Pt-ECSA of Pt\(_{x}\)Au\(_{y}\) Bimetallic NPs produced from PS\(_{n}\)-b-P4VP\(_{m}\) diblock copolymer template.

\(a\) - The mass loading of platinum was calculated relative to the signal generated for the ablated Sn from the well-defined ITO substrate. Complete ablation of the ITO layer (resting on float glass) beneath the Pt\(_{x}\)Au\(_{y}\) Bimetallic NPs catalyst layer was confirmed by monitoring the signals generated by the atomic constituents within the glass substrate (\(^{27}\)Na, \(^{24}\)Mg, \(^{28}\)Al, \(^{28}\)Si, \(^{29}\)Si, \(^{43}\)Ca).

The moles of \(^{118}\)Sn ablated during a single LA ICP-MS sample is:

\[
\text{counts}^{\text{195Pt}} \times \text{frac. conc. Sn in ITO} \times \text{frac. abund.}^{\text{118Sn}} \frac{0.1 \text{ Vol. ITO ablated} \times \text{Pro}}{\text{Molar Mass of ITO}}
\]

The mass loading of platinum is:

\[
\frac{\text{counts}^{\text{195Pt}}}{\text{frac. abund.}^{\text{195Pt}}} \times \frac{\text{mol}^{\text{118Sn}}}{\text{counts}^{\text{18Sn}}} \times \frac{\text{Pt Atomic Mass}}{\text{scan area}}
\]
Figure S13. (a) Steady-state cyclic voltammetry plots (100 mV/sec, 0.1 M H$_2$SO$_4$) for PtAu NPs synthesized from PS$_{1392}$-b-P4VP$_{471}$. (b) Steady-state cyclic voltammetry plots (100 mV/sec, 0.1 M H$_2$SO$_4$; 2M MeOH) for methanol oxidation using PtAu NPs synthesized from PS$_{552}$-b-P4VP$_{174}$. From top to bottom Pt$_{1.00}$Au$_{0.00}$, Pt$_{0.81}$Au$_{0.19}$, Pt$_{0.68}$Au$_{0.32}$, Pt$_{0.61}$Au$_{0.39}$, Pt$_{0.37}$Au$_{0.63}$ and Pt$_{0.00}$Au$_{1.00}$.

AFM and XPS analyses were used to confirm that samples prepared a polymer-overcasting and HF-etch procedure were similar in cluster definition and composition to those prepared directly on ITO electrodes (see Figure S16-S17 and Table S6-S7). The method involved transfer of the arrays of clusters of PtAu NPs to an ITO substrate from a floating polystyrene transfer layer created from relieving this layer from a sacrificial thermal oxide substrate (see experimental section). The transfer of a uniform and continuous PS layer bearing PtAu NPs onto the ITO substrate was complicated by the surface tension of the diluted HF$_{aq}$ and a drying artifact of the PS film. This affected the overall uniformity and density of the film but permitted enough material to be locally investigated by SFM and XPS. In the former, the dimensions for the periodicity and height of the array of PtAu NPs isolated from aurate and platinate loaded PS$_{552}$-b-P4VP$_{174}$ template created from the 88:12 Pt: Au immersion bath closely matched those in Table 1 (within 10%). In the latter, the overall signal for 4f electrons originating from the Pt and Au centers was less than that for a duplicate film prepared directly on ITO (without the floating and etching steps; see Figure S16). This reduced the overall signal to noise value which impacted the quality of the fit curves (see Figure S17). The values for the binding energies 4f electrons from Pt and Au for the fit curves and their areas are reported in Table S6 and S7, respectively. The approximate stoichiometry for PtAu NPs isolated from aurate and platinate loaded PS$_{1392}$-b-P4VP$_{471}$ template created from the direct route is Pt$_{0.41}$Au$_{0.59}$, an estimate that is with 10% of previously fabricated samples (see Table 2). The approximate stoichiometry for PtAu NPs isolated from aurate and platinate loaded PS$_{1392}$-b-P4VP$_{471}$ template created from the PS transfer route is Pt$_{0.54}$Au$_{0.46}$, an estimate that is with 10% of previously fabricated samples (see Table 2). Similarly, the agreement in the binding energies of 4f electrons from these two routes confirms that the overall oxidation state of the metals is similar in both cases (see Table S7).
Figure S16. Scanning force microscopy (SFM) image of arrays of clusters of PtAu NPs isolated from aurate and platinate loaded PS$_{552}$-b-P4VP$_{174}$ template using the 88:12 Pt:Au immersion bath. Prior to SFM, the array was overcoated with a polystyrene (PS) layer and then floated to an air-water interface using HF and then captured on a silicon substrate for Ar plasma. The in-plane dimensions of the image are 2µm x 2µm. The height scale at right ranges from 0 to 30 nm.

Figure S17. XPS comparison of ITO-supported arrays of clusters of PtAu NPs synthesized from PS$_{1392}$-b-P4VP$_{471}$ and the 88:12 platinate:aurate immersion bath isolated from direct preparation on an ITO substrate (top) and from preparation on silica substrate followed by embedding in polystyrene (PS) and transfer to ITO using HF and a final Ar plasma etch (see experimental section).
Table S6. Summary of binding energies of fitting curves from Figure S17 for 4f peaks for PtAu NPs synthesized from PS$_{1392}$-b-P4VP$_{471}$ and the 88:12 platinate:aurate immersion bath.
