Experimental Procedures

General Methods. All non-aqueous reactions were performed under argon in flame-dried glassware using dry solvents. Tetrahydrofuran was distilled from sodium/benzophenone. Benzene and triethylamine were distilled from calcium hydride. $n$-Butyllithium solutions in hexanes from Aldrich Chemical Company were titrated prior to use against diphenylacetic acid and used directly. Starting materials were purchased from Aldrich Chemical Company and used without further purification unless otherwise stated. Low temperature baths were ice/water (0 °C) and CO$_2$(C)/acetone (-78 °C). Reaction temperatures refer to that of the bath.

Reactions were monitored by thin layer chromatography (TLC) using commercial aluminum-backed silica gel sheets coated with silica gel 60 F$_{254}$ (E. Merck). TLC spots were developed by heating the plate after treatment with a phosphomolybdic acid (5%) containing a trace of ceric sulfate in aqueous sulfuric acid (5% v/v) or a solution of KMnO$_4$ in aqueous potassium hydroxide. Room temperature corresponds to 23 °C. Anhydrous magnesium sulfate (MgSO$_4$) and sodium sulphate (Na$_2$SO$_4$) was used to dry solutions in organic solvents. Excess solvents were removed (concentrated) in vacuo at pressures obtained by a water or air aspirator connected to a Büchi rotary evaporator. Trace solvents were removed on a vacuum pump. Product purification by flash chromatography was performed with E. Merck Silica Gel 60 (230-400 mesh) according to Still et al.$^1$ Preparative TLC (PTLC) was carried out on glass plates (20 x 20 cm) precoated (0.25 mm) with silica gel 60 F$_{254}$. Materials were detected by visualization under an ultraviolet lamp (254 nm) and/or by treating a 1 cm vertical strip removed from the plate with a solution of phosphomolybdic acid (5%) containing a trace of ceric sulfate in aqueous sulfuric acid (5% v/v), followed by charring on a hot plate.

Spectral Data. Melting points were determined with a Thomas-Hoover Unit melting point apparatus and are uncorrected. $^1$H NMR (500, 400 or 300 MHz) and $^{13}$C NMR (125, 100 or 75 MHz) spectra were recorded on a Bruker AVANCE 500, 400 or a 300 spectrometer. Chemical shifts are reported downfield from tetramethylsilane ($\delta$ scale) in ppm. $^1$H NMR data are reported as follows: Chemical shift (multiplicity, coupling constants (Hz), and integration).

---

Low resolution mass spectroscopy (MS) using electron impact (EI), were recorded on a V.G. Micromass 7070 HS mass spectrometer with an electron beam energy of 70 eV. High resolution mass spectroscopy (HRMS) were recorded on a Kratos Concept-11A mass spectrometer with an electron beam energy of 70 eV. IR spectra were recorded on a SHIMADZU FTIR-8400S spectrometer. The purity of all title compounds was judged to be >95% as determined by a combination of $^1$H NMR and $^{13}$C NMR analyses.

**Materials:** The preparations of the following compounds were described previously: $(E)$-5-bromopenta-1,3-diene \(^2\), \(1b\)^3, and \(2\). All other reagents were commercially available and unless otherwise noted, were used as received.

3-(tert-Butyldimethylsilyloxy)propanal (2) (0.50 g, 2.65 mmol) was dissolved in a mixture of DMF (3 mL) and H\(_2\)O (1.5 mL). 5-Bromo-1,3-pentadiene (0.78 g, 5.30 mmol) was then added and the solution was cooled to 0 °C. Indium metal (100 mesh, 0.61 g 5.30 mmol) was added portion-wise, and the reaction was warmed to 23 °C and stirred for 30 minutes. The reaction was then diluted with CH\(_2\)Cl\(_2\), poured into ether, filtered (5 cm high silica gel plug) with ether as eluent. Maleic anhydride (50 mg, 0.51 mmol) was added to a solution of the trienol 5 (32 mg, 0.26 mmol) in DCM (5 mL). After 24 h, the reaction mixture was concentrated. Purification by PTLC (50% ethyl acetate in hexane) gave solely adduct 9 (11 mg, 19%).
