C. Characterization of compounds 1-6 in solution by PGSE NMR

![Figure S21](image_url)  

**Figure S21.** Plot of $\ln(I/I_0)$ vs $Y^2\delta^2G^2[\Delta-(\delta/3)] \times 10^{10}$ (m$^{-2}$ s) from PGSE experiments (400 MHz, CD$_2$Cl$_2$, 25 °C, $\Delta$ = 80 ms, $\delta$ = 1.1 ms). The hydrodynamic radius ($r_H$) of each compound was calculated by using the slopes ($D_t$) of the linear fits. $I$ = intensity of the observed spin-echo, $I_0$ = intensity of the spin-echo in the absence of gradients, $G$ = varied gradient strength, $\Upsilon$ = gyromagnetic ratio ($2.675 \times 10^8$ rad s$^{-1}$ T$^{-1}$), $\delta$ = length of the gradient pulse, $\Delta$ = delay between the midpoints of the gradients.

Self-diffusion translational coefficients ($D_t$) were calculated graphically from the slopes of the linear best-fit lines.$^3$ The $c^sa r_H^sa$ value of each diffusing sample was estimated by the equation 1 which was derived from the advanced Stokes-Einstein equation 2. $r_H^sa$ was taken from the trend line of a plot, $c^sa r_H^sa$ vs. $r_H^sa$, based on the equation 4 reported by Chen and coworkers.$^4$

H. Homonuclear decoupled $^1$H NMR spectra

The $P_r$ and $P_m$ values were calculated from the following formulas which are based on tetrad probabilities in the polymerization of rac-lactide as calculated from Bernoullian statistics. The assignment for each tetrad’s chemical shift is based on the generally accepted values.

Equations used:

\[
[m\text{mm}]= (P_m)^2 + P_r P_m/2
\]

\[
[m\text{mr}]= P_r P_m/2
\]

\[
[r\text{mm}]*= P_r P_m/2
\]

\[
[r\text{mr}]*= (P_r)^2/2
\]

\[
[m\text{rm}]= ((P_r)^2 + P_r P_m)/2
\]

*Effectively only these two equations are used in the calculations as the other peaks cannot be accurately integrated.
