ABSTRACT: Transition-metal-free, sulfur mediated allylic C-H arylation, epoxidation and aziridination were realized through one-pot procedures. The reaction design involved initial addition between olefins and triflic anhydride activated sulfoxides, followed by subsequent reactions of the allylic sulfur ylides generated under basic conditions with arylboronic acids, aldehydes, or aldimines, to give allylic arylation, epoxidation or aziridination products, respectively.

The C–C bond formation at allylic positions has become attractive research topic for decades.¹ Apart from Alder ene type reactions, the most influential method for allylic functionalization is arguably the Tsuji-Trost type allylation. While palladium-catalyzed allylic substitutions enabled the synthesis of a broad range of molecules,² recent studies on palladium-catalyzed allylic C-H alkylation provided new opportunity for converting C-H bond directly to C-C bond at allylic positions.³ In addition, oxidative cross-dehydrogenative coupling reaction was another attractive alternative for allylic C-H functionalization.⁴ However, reports on allylic C-H arylation reactions were still rare in the literature, while most metal-catalyzed coupling of allyl electrophiles with aryl-partners required functionalized olefins.⁵ Nakamura and co-workers realized iron-catalyzed allylic arylation of simple olefins with aryl-Grignard reagents.⁶ MacMillan and Cuthbertson accomplished the direct arylation of allylic C-H bond by using cyanoarenes as coupling partner via dual photoredox and organocatalysis.⁷ Rueping's group reported direct allylic arylation of olefins with aryl- and vinylbromides by the combined use of nickel and visible light catalysis.⁸ Recently, Glorius and co-workers explored rhodium catalyzed allyl-aryl coupling of arylboron reagents or heteroarenes with unfunctionalized olefins.⁹ Herein, we report a transition-metal-free, sulfur mediated route for converting allylic C-H bond to C-C bond via the allylic sulfur ylide intermediates, which provides the arylation, epoxidation, and aziridination products in one-pot fashions (Scheme 1).¹⁰

Scheme 1. Sulfur mediated allylic C-H arylation, epoxidation, and aziridination reactions

Sulfur ylides have been widely used for synthetic chemistry since the pioneering work of Johnson, Corey and Chaykovsky in the 1960s.^{11a-d} Conventionally, there are two main methods for generating sulfur ylides: deprotonation of sulfonium salts, which are usually prepared through sulfide substitution of alkyl

halides; or alternatively, reaction between sulfides and metal carbenoids, which could be generated from metal-catalyzed decomposition of diazo compounds. Certain other strategies for the synthesis of sulfur ylides have also been explored.^{11e-l} Allylic and benzylic sulfur ylides, classified as semi-stabilized ylides, generally exhibited good reactivity in epoxidation or aziridination reactions with carbonyl or imine type compounds.¹² Asymmetric reaction of chiral sulfur ylides were also well-established.^{11a,11b,13} On the other hand, sulfur ylides could also react with organoboron reagents through 1,2-metalate shift of the corresponding ate complex.¹⁴ In 2018, Huang and co-workers further achieved sulfide catalyzed cross-coupling between benzyl halides and arylboronic acids.^{15a} Wang's group also reported a non-transition-metal catalyzed coupling between benzyl halides and arylboronic acids via Friedel-Crafts-type reaction pathway.^{15b} Based on many precedents for the reactions with alkenes and alkynes involving activated sulfoxides,^{16,17} we hypothesize that allylic sulfur ylides could be directly generated from simple olefins, through electrophilic addition of activated sulfoxides with olefins, followed by subsequent deprotonation, which could then react with arylboronic acids via 1,2-metalate shift and hydrolysis, or with aldehydes/aldimines via Corey-Chaykovsky reaction to give the desired allylic functionalized products (Scheme 1).

Reaction conditions: a solution of **1a** (0.4 mmol) and sulfoxide (**2**) in 1 mL of solvent was treated Tf₂O (0.48 mmol) at 0 °C, added base (1 mmol) and 4-methoxyphenyl boronic acid (1 mmol), and warmed up, stirred for overnight. ^aIsolated yield after column chromatography. ^bInstead of adding Tf₂O at 0 °C, step 1 was conducted at -78 °C. ^cMicrowave heating in sealing tube. ^dInstead of adding Tf₂O at 0 °C, step 1 was conducted at -43 °C. ^eUsing 2 mL of solvent (0.2 M in **1a**). ^fReaction conducted at 1 mmol scale.

We initially optimized the conditions for allylic C-H arylation of α -methylstyrene (**1a**) (Table 1). The formation of allylic sulfonium salt through electrophilic addition between α -methylstyrene (**1a**) and triflic anhydride activated sulfoxides (**2**) took place in step 1. After that, boronic acid **3a** and base were added to complete the transformation in step 2. It was found that inorganic base worked better than strong organic base (i.e. DBU, entry 1) for this transformation, affording desired product **4a** (entries 2-4) at room temperature. Instead of dichloromethane (DCM), toluene or dichloroethane (DCE) could also be used as solvent for this reaction, and thus allowing increased reaction temperature for step 2 (entries 5-7, 12). Although higher temperature exhibited the potential of promoting yields, it also facilitated other competitive side reactions. In order to avoid the major side product, which was formed through [3,3]-sigmatropic rearrangement of allylic sulfonium intermediates and then rearomatization (Table 2C),^{16f,16n} we tried using different sulfoxides bearing either electron-donating or electron-withdrawing groups at the phenyl rings' para-position (entries 8-11). Gratifyingly, it was found that bis(4-chlorophenyl) sulfoxide (**2c**) could adequately suppress such unintended rearrangement. When reaction concentration was lowered to 0.2 M, such optimal

condition achieved 92% yield of arylation product **4aa** (entry 13).

We then explored the substrate scope of different arylboronic acids (Table 2A) under the optimized conditions. This arylation protocol worked nicely for electron-rich arylboronic acids, e.g. *para*-alkyloxy substrates gave the corresponding products **4aa-4ae** in 82% to 92% yields, while less electron-rich arylboronic acids gave products **4af**, **4ag**, and **4ai** with lower yields. For electron-rich heterocyclic boronic acids, furan-3-boronic acid only gave desired product **4ah** in 35% yield. Halogen substituted products **4al** and **4am** were obtained in 56% and 62% yields, respectively. However, arylboronic acids with strong electron-withdrawing groups gave no desired product (see supporting information for details). Protodeboronation of those boronic acids was predominant under our current reaction conditions. Presumably, 1,2-migration of the aryl group on boron-ate complex (see our proposed reaction mechanism in Scheme 1) would be less favored for electron-deficient aryl groups. Next, we evaluated a variety of substituted α -methylstyrenes, and the desired products **4ba-4ha** were isolated in 42% to 86% yields (Table 2B). In addition, isoprene (**1k**) and cyclohexene (**1n**) could also afford the coupling products **4ka** and **4na** in 37% and 31% yields, respectively. For alkenes **1l** and **1m** with exocyclic methylene groups, it was found that bis(4-methoxyphenyl) sulfoxide (**2b**) favored this transformation, since its electron-rich aryl group on the sulfur atom probably enhanced the stability of corresponding sulfonium intermediate. Furthermore, tri-substituted alkenes failed to give the desired products (see supporting information for details), presumably, the corresponding allylic sulfur ylides formed from tri-substituted olefins were steric hindered to participate in these reactions

For the allylic C-H epoxidation or aziridination reactions, another set of reaction condition was optimized, and DBU was found to be most suitable base for generating sulfur ylides in situ to participate in the Corey-Chaykovsky type reactions (see supporting information for details). The substrate scope and side reactions were shown in Table 3. Electron-deficient aromatic aldehydes afforded major *trans*-epoxide **6ab-6ag** in moderate yields with 3:1-4:1 dr (Table 3A). *Meta*-methoxy substituted aromatic aldehyde only gave 31% yield of *trans*-**6ai**. When trying some electron-rich aromatic aldehydes, the corresponding allylic epoxide products were prone to decompose in acidic condition. Meanwhile, a variety of electron-rich and electron-deficient α -methylstyrenes **1a-1j** were also tolerated, affording major *trans*-epoxides products in 24% to 65% yields with moderate dr (Table 3B). In addition, Isoprene (**1k**) afforded major *trans*-**6kg** in 46% with excellent dr. The use of alkenes **1l** and **1m** with exocyclic methylene group afforded *trans*-**6lg** and *trans*-**6mg** in lower yields with poor dr. We tried to enhance the diastereoselectivity by using different sulfoxides, but achieved no significant improvement (see supporting information for details). Similarly, *N*-tosyl aldimines provided allylic aziridination products **8aa-8aj** in moderate yields and dr (Table 3C). In those cases, ring expansion rearrangement of allylic aziridine products toward dihydropyrroles partly contributed to the diminished yields (Table 3D).¹⁸

In conclusion, we have developed a novel sulfur mediated allylic C-H functionalization strategy to access arylation, epoxidation or aziridination products without the involvement of transition metal or photoredox catalysts. The use of readily available reagents under robust reaction condition is an attractive feature of this chemistry.

EXPERIMENTAL SECTION

General Information. All reactions were carried out in oven-dried glassware under a nitrogen atmosphere employing standard techniques unless otherwise noted. Dichloromethane was refluxed over CaH₂, and freshly distilled prior to use. Flash column chromatography was performed using silica gel (normal phase, 200-300 mesh). Petroleum ether used for column chromatography were 60-90 °C fraction, and the removal of residue solvent was accomplished under rotovap with repeated azeotrope with chloroform, and then evaporation under vacuum (< 1 mmHg pressure). Reactions were monitored by thin-layer chromatography on silica gel 60-F254 coated 0.2 mm plates. The plates were visualized under UV light. ¹H and ¹³C NMR

spectra were recorded on a 400 MHz spectrometer, usually in CDCl₃ with TMS as an internal standard, and the chemical shifts (δ) were reported in parts per million (ppm). The IR spectra (KBr pellets, ν [cm⁻¹]) were taken on a FTIR spectrometer. HRMS measurements were carried out on a TOF mass spectrometer. Preparation of *N*-tosylaldimine **7j:** To the solution of the 4-(methylthio)benzaldehyde (5 mmol, 1 equiv) in PhMe (30 mL) was added TsNH₂ (5 mmol, 1 equiv) and BF₃·Et₂O (0.06 ml, 0.5 mmol, 0.1 equiv). The mixture was refluxed using a Dean-Stark apparatus for 20 h. After the reaction was complete as monitored by TLC, the solution was cooled to room temperature, concentrated under reduced pressure, and recrystallized from EtOAc/Hexanes.

General Procedure A for arylation product: To a flame-dried 10 mL tube, alkene (**1**) (0.4 mmol) and bis(4-chlorophenyl) sulfoxide (**2b**) (131 mg, 0.48 mmol) were added, and then dissolved with toluene (2 mL) under nitrogen atmosphere before cooling down to 0 °C. T₂O (81 μ L, 0.48 mmol) were added dropwise and kept 15 minutes, then K₃PO₄·3H₂O (266 mg, 1 mmol) and arylboronic (**3**) (1 mmol) was added. After fully stirred, warm up to 110 °C, and kept 12 hours of reaction at reflux temperature. The solution was quenched by 10 mL water, and then the aqueous phase extracted with CH₂Cl₂ (10 mL×3). The combined organic phases were dried with Na₂SO₄ and concentrated under reduced pressure to give the crude products. The crude product was then purified by repeated flash column chromatography and preparative thin layer chromatography to give pure isolated products. If some pure products are hard to separate from sulfide, Oxone (0.8 mmol) could add to a solution of crude product in MeOH (10 mL). After the reaction was complete as monitored by TLC, the solution was quenched by saturated sodium bicarbonate, and then aqueous phase extracted with CH₂Cl₂ (10 mL×3). The combined organic phases were dried with Na₂SO₄ and concentrated under reduced pressure to give the crude products for further purification.

General Procedure B for epoxidation product: To a flame-dried Schlenk tube, alkene (**1**) (47 mg, 0.4 mmol) and diphenyl

sulfoxide (**2a**) (97 mg, 0.48 mmol) were added, and then dissolved with dichloromethane (2 mL) under nitrogen atmosphere before cooling down to -78 °C (liquid nitrogen/ethyl acetate bath). TF_2O (81 μL , 0.48 mmol) were added dropwise and kept 15 minutes. Then DBU (143 μL , 0.48 mmol) and aldehyde (0.6 mmol) was added. After 12 hours of reaction at -78 °C and warm up slowly to room temperature. the solution was quenched by 10 mL water. The aqueous phase extracted with CH_2Cl_2 (10 mL \times 3). The combined organic phases were dried with Na_2SO_4 and concentrated under reduced pressure to give the crude products. Crude $^1\text{H NMR}$ was taken for determination of diastereomer ratio (see SI page 67-76 for the characteristic peaks used for dr determination). The crude product was then purified by repeated flash column chromatography and preparative thin layer chromatography to give pure isolated products.

2-Phenyl-3-(1-phenylvinyl)oxirane (trans-) (6aa): yellow oil (40%, 35mg), $R_f = 0.58$ (petroleum ether/ethyl acetate = 15:1), was synthesized according to General Procedure B; $^1\text{H NMR}$ (400 MHz, $\text{DMSO}-d_6$) δ 7.56 – 7.30 (m, 10H), 5.63 (s, 1H), 5.43 (s, 1H), 3.96 (s, 1H), 3.87 (s, 1H); $^{13}\text{C}\{^1\text{H}\}$ NMR (100 MHz, $\text{DMSO}-d_6$) δ 144.6, 138.1, 137.7, 129.6, 129.5, 129.3, 129.2, 126.9, 126.6, 112.6, 62.3, 61.5; IR (KBr) ν (cm^{-1}) 2918, 1629, 1560, 1164, 1025, 878, 806, 668; HRMS (ESI) calcd for $\text{C}_{16}\text{H}_{15}\text{O}^+$ $[\text{M}+\text{H}]^+$ m/z 223.1117, found 223.1110.

General Procedure C for aziridination product: To a flame-dried Schlenk tube, alkene (**1**) (0.4 mmol) and diphenyl sulfoxide (**2a**) (97 mg, 0.48 mmol) were added, and then dissolved with acetonitrile (2 mL) under nitrogen atmosphere before cooling down to -43 °C (liquid nitrogen/acetonitrile bath). Ti_2O (81 μL , 0.48 mmol) were added dropwise and kept 15 minutes, Then DBU (143 μL , 0.48 mmol) and imine (**7**) (0.6 mmol) was added. After 12 hours of reaction at -43 °C and warm up slowly

to room temperature, the solution was quenched by 10 mL water. The aqueous phase extracted with CH_2Cl_2 (10 mL \times 3). The combined organic phases were dried with Na_2SO_4 and concentrated under reduced pressure to give the crude products. Crude ^1H NMR was taken for determination of diastereomer ratio, Crude ^1H NMR was taken for determination of diastereomer ratio (see SI page 77-81 for the characteristic peaks used for dr determination). The crude product was then purified by repeated flash column chromatography (alumina) and preparative thin layer chromatography to give pure isolated products.
