Abstract

We study the expressiveness and the complexity of static analysis of extended conjunctive regular path queries (ECRPQs), introduced by Barceló et al. (PODS ’10). ECRPQs are an extension of conjunctive regular path queries (CRPQs), a well-studied language for querying graph structured databases. Our first main result shows that query containment and equivalence of a CRPQ in an ECRPQ is undecidable. This settles one of the main open problems posed by Barceló et al. As a second main result, we prove a non-recursive succinctness gap between CRPQs and the CRPQ-expressible fragment of ECRPQs. Apart from this, we develop a tool for proving inexpressibility results for CRPQs and ECRPQs. In particular, this enables us to show that there exist queries definable by regular expressions with backreferencing, but not expressible by ECRPQs.

1. Introduction

Many application areas (e.g., concerning the Semantic Web or biological applications) consider graph structured data, where the data consists of a finite set of nodes connected by labeled edges. For querying such data, one usually needs to specify types of paths along which nodes are connected. A widely studied class of queries for graph structured databases are the conjunctive regular path queries (CRPQs) (cf., e.g., [4, 6, 7]), where types of paths can be described by regular expressions specifying labels along the paths. For modern applications, however, also more expressive query languages are desirable, allowing not only to specify regular properties of path labels, but also to compare paths based on, e.g., their lengths, labels, or similarity.

To start a formal investigation of such concepts, Barceló et al. introduced the class of extended conjunctive regular path queries (ECRPQs), allowing to use not only regular languages to express properties of individual paths, but also regular relations among several paths, capable of expressing certain associations.
between paths. The authors of [3] investigated the complexity of query evaluation and static analysis of ECRPQs. While query containment is known to be decidable and EXPSPACE-complete for CRPQs [7, 4], it was shown to be undecidable for ECRPQs [3]. However, checking containment of an ECRPQ in a CRPQ still is decidable and EXPSPACE-complete [3]. (Un)Decidability of checking containment (or, equivalence) of a CRPQ in an ECRPQ was posed as an open question in [3].

In the present paper, we answer this question by showing that containment of a CRPQ in an ECRPQ is undecidable — even if the ECRPQ is, in fact, a CRPQ extended only by relations for checking equality of path labels (or, similarly, equal lengths of paths). Our proof proceeds by (a) simulating Turing machine runs by so-called H-systems, a concept from formal language theory generalizing pattern languages, and (b) using CRPQs and ECRPQs to represent languages described by H-systems. Our proof generalizes to (i) the case where one of the two queries is fixed, (ii) the case where all queries are Boolean and acyclic, and (iii) the problem of deciding equivalence rather than containment of CRPQs and ECRPQs.

Apart from the static analysis of queries, the present paper also investigates the expressiveness and succinctness of ECRPQs. Using the machinery developed for proving our undecidability results concerning static analysis, we show that CRPQ-definability of a given ECRPQ is undecidable, and that there is no recursive function \( f \) such that every CRPQ-definable ECRPQ of length \( n \) is equivalent to a CRPQ of length \( f(n) \).

Concerning the expressivity of (E)CRPQs, to the best of our knowledge, tools for showing inexpressibility results have not been presented in the literature yet. We develop such tools, enabling us to show, for example, that no ECRPQ-query can return exactly those tuples of nodes between which there is a path whose length is a composite number (i.e., a number of the form \( mn \) for \( n, m \geq 2 \)). Since these paths can be easily described by a regular expression with backreferencing (cf. [1, 8]) of the form \( (aa^+)\%x^+ \), this refutes a claim of [3] stating that all regular expressions with backreferencing can be expressed by ECRPQs.

**Structure of the paper.** We start with the necessary notations and definitions in Section 2 where, in particular, the syntax and semantics of ECRPQs (and restrictions thereof) are defined. Section 3 is devoted to the static analysis of ECRPQs and CRPQs, showing that containment and equivalence of CRPQs in ECRPQs are undecidable. Section 4 investigates the relative succinctness between CRPQs and CRPQ-expressible ECRPQs and provides tools for proving limitations to the expressive power of CRPQs and ECRPQs.

2. Preliminaries

Let \( \mathbb{N} \) denote the set of non-negative integers. We denote the *empty word* by \( \varepsilon \). Let \( A, B \) be alphabets. A *morphism* (between \( A^* \) and \( B^* \)) is a function \( h : A^* \to B^* \) with \( h(uv) = h(u)h(v) \) for all \( u, v \in A^* \). For every word \( w \in A^* \),...
$|w|$ stands for the length of $w$, and for every letter $a \in A$, $|w|_a$ denotes the number of occurrences of $a$ in $w$.

2.1. DB-Graphs and Queries.

A $\Sigma$-labeled $db$-graph is a directed graph $G = (V, E)$, where $V$ is a finite set of nodes, and $E \subseteq V \times \Sigma \times V$ is a finite set of directed edges with labels from $\Sigma$. A path $p$ between two nodes $v_0$ and $v_n$ in $G$ with $n \geq 0$ is a sequence $v_0 \cdot v_1 \cdot \ldots \cdot v_{n-1} \cdot v_n$ with $v_0, \ldots, v_n \in V$, $a_1, \ldots, a_n \in \Sigma$, and $(v_i, a_{i+1}, v_{i+1}) \in E$ for $0 \leq i < n$. We define the label $\lambda(p)$ of the path $p$ by $\lambda(p) := a_1 \cdot \ldots \cdot a_n$. Furthermore, for every $v \in V$, we define the empty path $v \varepsilon v$, with $\lambda(v \varepsilon v) = \varepsilon$.

A central concept considered in the present paper are regular relations (cf. [3] and the references therein). Let $\Sigma$ be a finite alphabet, let $\bot \notin \Sigma$, and let $\Sigma_\bot := \Sigma \cup \{ \bot \}$. Let $w = (w_1, \ldots, w_k) \in (\Sigma^*)^k$, where $w_i = a_{i,1} \ldots a_{i,|w_i|}$ (and all $a_{i,j} \in \Sigma$). We define the string $[w] \in (\Sigma^*)^k$ by $[w] := b_1 \cdots b_n$, where $n$ is the maximum of all $|w_i|$, and $b_j := (b_{j,1}, \ldots, b_{j,k})$, with $b_{j,i} = a_{i,j}$ if $j \leq |w_i|$, and $b_{j,i} = \bot$ if $j > |w_i|$. In other words, $[w]$ is obtained by aligning all $w_i$ to the left, and padding the unfilled space with $\bot$ symbols. A $k$-ary relation $R \subseteq (\Sigma^*)^k$ is called regular if the language $\{[\tau] \mid \tau \in R\}$ is regular.

Obviously, every regular language is a (unary) regular relation. In addition to this, the present paper focuses on the following $k$-ary regular relations ($k \geq 2$):

1. the equality relation $eq := \{(w_1, \ldots, w_k) \mid w_1 = \ldots = w_k\}$,
2. the length equality relation $el := \{(w_1, \ldots, w_k) \mid |w_1| = \ldots = |w_k|\}$.

Note that each of these relations needs to be defined w. r. t. a finite alphabet $\Sigma$, which we usually omit for the sake of brevity.

We now define ECRPQs and CRPQs, following the definitions from [3]. Fix a countable set of node variables and a countable set of path variables. Let $\Sigma$ be a finite alphabet. An extended conjunctive regular path query (ECRPQ) $Q$ over $\Sigma$ is an expression of the form

$$\text{Ans}(\pi, \chi) \leftarrow \bigwedge_{1 \leq i \leq m} (x_i, \pi, y_i), \bigwedge_{1 \leq j \leq l} R_j(\omega_j),$$

such that $m \geq 1, l \geq 0$, and

1. each $R_j$ is a regular expression that defines a regular relation over $\Sigma$,
2. $\pi = (x_1, \ldots, x_m)$ and $\gamma = (y_1, \ldots, y_m)$ are tuples of (not necessarily distinct) node variables,
3. $\pi = (\pi_1, \ldots, \pi_m)$ is a tuple of distinct path variables,
4. $\omega_1, \ldots, \omega_l$ are tuples of path variables, such that each $\omega_j$ is a tuple of variables from $\pi$, of the same arity as $R_j$,
5. $\pi$ is a tuple of node variables among $\pi$, $\gamma$, and
\[ \chi \text{ is a tuple of path variables among those in } \pi. \]

The expression \( \text{Ans}(\chi, \chi) \) is the head, and the expression to the right of \( \leftarrow \) is the body of \( Q \). If \( \chi \) and \( \chi \) are the empty tuple (i.e., the head is of the form \( \text{Ans}() \)), \( Q \) is a Boolean query. The relational part of an ECRPQ \( Q \) is \( \bigwedge_{1 \leq i \leq m} (x_i, \pi_i, y_i) \), and the labeling part is \( \bigwedge_{1 \leq j \leq l} R_j(\omega_j) \). We denote the set of node variables in \( Q \) by \( \text{nvar}(Q) \).

Intuitively, all variables are quantified existentially, and the words formed by the labels along the paths have to satisfy the respective relations. Formally, for every \( \Sigma \)-labeled \( db \)-graph \( G \), every ECRPQ \( Q \) (of the form described in (1)) over \( \Sigma \), every mapping \( \sigma \) from the node variables of \( Q \) to nodes in \( G \), and every mapping \( \mu \) from the path variables of \( Q \) to paths in \( G \), we write \( (G, \sigma, \mu) \models Q \) if

1. \( \mu(\pi_i) \) is a path from \( \sigma(x_i) \) to \( \sigma(y_i) \) for every \( 1 \leq i \leq n \),
2. for each \( \omega_j = (\pi_{j1}, \ldots, \pi_{jk_j}), 1 \leq j \leq l \), the tuple \( (\lambda(\mu(\pi_{j1})), \ldots, \lambda(\mu(\pi_{jk_j}))) \)
   belongs to the relation \( R_j \).

Finally, we define the output of \( Q \) (of the form described in (1)) on \( G \) by

\[ Q(G) := \{ (\sigma(\chi), \mu(\chi)) \mid \sigma, \mu \text{ such that } (G, \sigma, \mu) \models Q \}. \]

As usual, if \( Q \) is Boolean, we model the Boolean constants \( \text{true} \) and \( \text{false} \) by the empty tuple (\( () \)) and the empty set \( \emptyset \), respectively. In other words, \( Q(G) = \text{true} \) iff there exist assignments \( \sigma \) and \( \mu \) with \( (G, \sigma, \mu) \models Q \).

Two queries \( Q \) and \( Q' \) are called equivalent (\( Q \equiv Q' \), for short) if \( Q(G) = Q'(G) \) for all \( db \)-graphs \( G \). A query \( Q \) is said to be contained in a query \( Q' \) (\( Q \subseteq Q' \), for short) if \( Q(G) \subseteq Q'(G) \) for all \( db \)-graphs \( G \).

With an ECRPQ \( Q \) we associate an edge-labeled directed graph \( H_Q^{\text{lab}} \) whose vertex set is the set of node variables occurring in \( Q \), and where there is an edge from \( x \) to \( y \) labeled \( \pi \) iff \( (x, \pi, y) \) occurs in the relational part of \( Q \). As in (3), we write \( H_Q \) to denote the (unlabeled) directed graph obtained from \( H_Q^{\text{lab}} \) by deleting the edge-labels (and removing duplicate edges). A query \( Q \) is called acyclic if \( H_Q \) is acyclic.

In accordance with (3), a conjunctive regular path query (CRPQ) \( Q \) over \( \Sigma \) is an ECRPQ over \( \Sigma \) of the form described in (1), where all relations \( R_j \) are unary relations, and (hence), all tuples \( \omega_j \) are singletons.

Thus, CRPQs can only refer to the languages that are allowed to occur along the paths, while ECRPQs can also describe relations between different paths.

The present paper devotes special attention to two classes of queries with an expressive power that lies strictly between CRPQs and ECRPQs: A CRPQ with equality relations is an ECRPQ where every relation in the labeling part is either of arity 1 (i.e., a regular language), or a \( k \)-ary eq-relation for some \( k \geq 2 \). Analogously, a CRPQ with equal length relations is an ECRPQ where every relation in the labeling part is either of arity 1, or a \( k \)-ary el-relation.

It is easy to see that ECRPQs and CRPQs can be transformed into queries in the following normal forms (note, though, that these transformations might increase the size of the queries):

\[ Q(G) := \{ (\sigma(\chi), \mu(\chi)) \mid \sigma, \mu \text{ such that } (G, \sigma, \mu) \models Q \}. \]
Lemma 2.1. For every ECRPQ $Q = \text{Ans}(\overline{z}, \overline{y}) \leftarrow \bigwedge_{1 \leq i \leq m} (x_i, \pi_i, y_i), \bigwedge_{1 \leq j \leq l} R_j(z_j)$, there exists a regular relation $R$ of arity $m$ such that $Q$ is equivalent to the ECRPQ $Q' := \text{Ans}(\overline{z}, \overline{y}) \leftarrow \bigwedge_{1 \leq i \leq m} (x_i, \pi_i, y_i), R(\pi_1, \ldots, \pi_m)$.

Proof. As every relation $R_i$ of arity $m_i$ can be interpreted as a regular language over the alphabet $\{a, \perp\}^{m_i}$ that is recognized by some finite automaton $M_i$, one can obtain the relation $R$ from these $R_i$ by letting $m$ be the maximum of all the $m_i$ and by constructing a finite automaton $M$ over the alphabet $\{a, \perp\}^m$ that simulates all $M_i$ in parallel. □

Lemma 2.2. For every CRPQ $Q = \text{Ans}(\overline{z}, \overline{y}) \leftarrow \bigwedge_{1 \leq i \leq m} (x_i, \pi_i, y_i), \bigwedge_{1 \leq j \leq l} L_j(\pi_i)$ (where $i_j \in \{1, \ldots, m\}$), there exist regular languages $L_1', \ldots, L_m' \subseteq \Sigma^*$ such that $Q$ is equivalent to the CRPQ $Q' := \text{Ans}(\overline{z}, \overline{y}) \leftarrow \bigwedge_{1 \leq i \leq m} (x_i, \pi_i, y_i), \bigwedge_{1 \leq i \leq m} L_i'(\pi_i)$.

Proof. Let $Q$ be a CRPQ over $\Sigma$. For every path variable $\pi_i$, $1 \leq i \leq m$, we define $I_i := \{ j \mid i_j = i \}$. We construct the labeling part $Q'$ by defining atoms $L_i'(\pi_i)$ for $1 \leq i \leq m$ in the following way:

1. If $I_i$ is empty, let $L_i' := \Sigma^*$,
2. if $I_i$ contains exactly one element $j$, let $L_i' := L_j$,
3. if $I_i$ contains more than one element, let $L_i' := \bigcap_{j \in I_i} L_j$. As every language $L_j$ is regular, $L_i'$ is also regular.

The relational part of $Q'$ is identical to the relational part of $Q$; and it is easy to see that $Q \equiv Q'$ holds. □

Hence, for ECRPQs it suffices to consider just one regular relation of arity $m$; and for CRPQs, it suffices to consider just one regular language per path variable.

2.2. Turing Machines and H-Systems

Let $\mathcal{M}$ be a (deterministic) Turing machine with state set $Q$, initial state $q_0 \in Q$, halting state $q_H \in Q$, tape alphabet $\Gamma$ (including the blank symbol), such that $Q \cap \Gamma = \emptyset$, and an input alphabet $\Gamma_I \subset \Gamma$ that does not include the blank symbol. We adopt the conventions that $\mathcal{M}$ accepts by halting, and does not halt in the first step (i.e., $q_0 \neq q_H$).

A configuration of $\mathcal{M}$ is a word $w_1qw_2$, with $w_1, w_2 \in \Gamma^*$ and $q \in Q$. We interpret $w_1qw_2$ as $\mathcal{M}$ being in state $q$, while the tape contains $w_1$ on the left side, and $w_2$ on the right side. The head is on the position of the first (leftmost) letter of $w_2$ (if $w_2 = \varepsilon$, $\mathcal{M}$ reads the blank symbol). We denote the successor relation on configurations of $\mathcal{M}$ by $\vdash_{\mathcal{M}}$. An accepting run of $\mathcal{M}$ is a sequence $C_0, \ldots, C_n$ of configurations of $\mathcal{M}$ (with $n \geq 1$), such that $C_0 \in q_0\Gamma_I^n$ ($C_0$ is
Definition 2.3. An restricted version of the H-systems introduced by Albert and Wegner [2].

be viewed as a generalization of pattern languages (cf. Salomaa [15]), or as a initial configuration), and

where (i) \( X \) and \( \Sigma \) are finite, disjoint alphabets, (ii) \( \mathcal{L} \) is a function that maps every \( x \in X \) to a regular language \( \mathcal{L}(x) \subseteq \Sigma^* \) with \( \varepsilon \in \mathcal{L}(x) \), and (iii) \( \alpha \in (X \cup \Sigma)^+ \).

A morphism \( h : (\Sigma \cup X)^* \rightarrow \Sigma^* \) is H-compatible if \( h(a) = a \) for every \( a \in \Sigma \), and \( h(x) \in \mathcal{L}(x) \) for every \( x \in X \). We then define the language \( L(H) \) that is generated by \( H = (\Sigma, X, \mathcal{L}, \alpha) \) as \( L(H) := \{ h(\alpha) \mid h \text{ is an H-compatible morphism} \} \).

For every finite, nonempty set of H-systems \( \mathcal{H} = \{ H_1, \ldots, H_k \} \), we define \( L(\mathcal{H}) = \bigcup_{i=1}^{k} L(H_i) \).

In other words, the letters from \( \Sigma \) are constants, the letters from \( X \) are variables, and \( L(H) \) is obtained from \( \alpha \) by uniformly replacing every variable \( x \) with a word from \( \mathcal{L}(x) \). We assume w.l.o.g. that \( X \) is chosen minimally; i.e., every \( x \in X \) occurs in \( \alpha \). It is easy to see that H-systems are able to generate non-regular languages; e.g., the system \( H = (\Sigma, \{ x \}, \mathcal{L}, xx) \) with \( \mathcal{L}(x) = \Sigma^* \) generates the language of all \( wwx \), \( w \in \Sigma^* \). We use unions of H-system languages to describe the sets \( \text{INVALC}(\mathcal{M}) \):

Lemma 2.4. Given a Turing machine \( \mathcal{M} \), one can effectively construct a set \( \mathcal{H} = \{ H_1, \ldots, H_k \} \) of H-systems (for some \( k \geq 1 \)) such that \( \text{INVALC}(\mathcal{M}) = L(\mathcal{H}) \).

Proof. Let \( \mathcal{M} \) be a Turing machine with state set \( Q \) and tape alphabet \( \Gamma \), and define \( \Sigma := \Gamma \cup Q \cup \{ \# \} \). We approach the process of defining \( \mathcal{H} \) from the following angle: Every word \( w \in \text{INVALC}(\mathcal{M}) \) contains at least one error that prevents \( w \) from being an element of \( \text{VALC}(\mathcal{M}) \). Most of these conditions can be described by a regular languages; e.g, if

\[
w \notin \#q0(\Gamma^*)\ldots\#\Gamma^*q\Gamma^*\ldots\#\Gamma^*q\mu\Gamma^*\#,
\]

\( w \) is not an encoding of a sequence of configurations of \( \mathcal{M} \), or it is such an encoding, but the first configuration is not an initial configuration, or the last configuration is not a halting configuration. Hence, we can define a H-System
$H_1 := (\Sigma, \{x\}, \mathcal{L}_1, x)$, where $\mathcal{L}_1$ maps $x$ to the complement of the language

$$\#q_0(\Gamma_1)^* (\#\Gamma^* Q \Gamma^*)^* \#\Gamma^* q_\mu \Gamma^* \#.$$  

Thus, if $w \notin L(H_1)$, we know that $w$ is an encoding of configurations $C_0, \ldots, C_n$ for some $n \geq 1$, such that $C_0$ is an initial configuration, and $C_n$ is a halting configuration. All that remains is to describe all possible transition errors, i.e., $C_i, C_{i+1}$ for which $C_i \vdash_M C_{i+1}$ does not hold. Most of these errors can be described using only regular languages, e.g., if when reading some $a \in \Gamma$ in a state $q \in Q$, $M$ is supposed to enter a state $p \in Q$, we can describe all errors in the transition of states using an H-system $H = (\Sigma, \{x\}, \mathcal{L}, x)$, where

$$\mathcal{L}(x) := \Sigma^* \#\Gamma^* qa \Gamma^* \# \Gamma^*(Q \setminus \{p\}) \Sigma^*.$$  

It is easy to see that $w \in L(H) \setminus L(H_1)$ if and only if $w$ includes a sequence of configurations that contains a transition with the aforementioned error. All other state transition errors can be described analogously, as can be all errors regarding the symbols that $M$ is supposed to write. For example, if $M$ reads some $a \in \Gamma$ while in state $q \in Q$ and is supposed to write some $b \in \Gamma$, move the head to the right, and enter some state $p \in Q$, the regular language

$$\Sigma^* \#\Gamma^* qa \Gamma^* \# \Gamma^*(\Gamma \setminus \{b\}) p \Sigma^*$$  

describes all errors where a symbol other than $b$ was written.

Of course, as INVALC($M$) can be non-regular (if dom($M$) is infinite), regular languages alone are not sufficient to describe all possible errors in a run of $M$. More specifically, we cannot handle arbitrary errors in the preservation of the tape contents from one configuration to the other. Again, assume $M$ reads some $a \in \Gamma$ while in state $q \in Q$ and is supposed to write some $b \in \Gamma$, move the head to the right, and enter some state $p \in Q$. In all these cases, a configuration $C = w_1 qaw_2$ with $w_1, w_2 \in \Gamma^*$ is followed by the configuration $C' = w_1 bpw_2$.

Our goal is to define H-expressions that capture all cases where the encoding of configurations $C_0, \ldots, C_n$ contains configurations $C_i = w_1 qaw_2, C_{i+1} = w_3 bpw_4$ where $w_1 \neq w_3$, or $w_2 \neq w_4$ holds (with $w_1, \ldots, w_4 \in \Gamma^*$). Note that, for all words $w, w' \in \Gamma^*$, $w \neq w'$ holds if and only if there exist words $u, v, v' \in \Gamma^*$ and letters $c, d \in \Gamma$ with $c \neq d$, $w = ucv$, and $w' = udv'$, or exactly one of $w, w'$ is the empty word.

As errors described in the latter case (i.e., that exactly one of $w_1, w_3$ or of $w_2, w_4$ is empty) can be expressed using regular languages, we focus our explanation on the former case. In order to express these errors, for every $c \in \Gamma$, we define languages

$$L_{c,1} := \bigcup_{v \in \Gamma^*} \Sigma^* \# v \Gamma^* qa \Gamma^* \# v (\Gamma \setminus \{c\}) \Sigma^*,$$

$$L_{c,2} := \bigcup_{v \in \Gamma^*} \Sigma^* \#\Gamma^* qa v \Gamma^* \#\Gamma^* bp v (\Gamma \setminus \{c\}) \Sigma^*.$$ 

7
These languages can be generated by H-systems, e.g., the system \((\Sigma, X, L, \alpha)\) with \(X = \{x_1, x_2, x_3, x_4\}\), \(\alpha = x_1x_2x_3x_2x_4\) and
\[
\begin{align*}
L(x_1) &= \Sigma^*\#, \\
L(x_2) &= \Gamma^*, \\
L(x_3) &= c\Gamma^*qa\Gamma^*\#, \\
L(x_4) &= (\Gamma \setminus \{c\})\Sigma^*.
\end{align*}
\]
generates \(L_{c,1}\). If \(M\) is supposed to move to the left instead of to the right, the corresponding H-expressions can be defined analogously. Hence, by defining appropriate H-expressions for all possible tape letters \(a \in \Gamma\) and states \(q \in Q\) and the corresponding actions of \(M\), \(H\) can be constructed effectively. \(\square\)

As we shall see in the next section, it is possible to reduce decision problems on finite unions of H-systems (and, hence, on the domains of Turing machines) to decision problems on CRPQs and ECRPQs.

3. Query Containment and Equivalence

3.1. Query Containment

The query containment problem is the problem to decide for two input queries \(Q\) and \(Q'\) whether \(Q \subseteq Q'\).

The containment of CRPQs in CRPQs and of ECRPQs in CRPQs is known to be decidable and \(\text{ExpSpace}\)-complete (cf. [7] and [3], resp.). In [3], the authors proved the undecidability of the containment problem for ECRPQs, and mentioned the decidability of containment of CRPQs in ECRPQs as an important open problem. Our first main result states that this problem is undecidable, even if the ECRPQs are of a comparatively restricted form:

**Theorem 3.1.** For every alphabet \(\Sigma\) with \(|\Sigma| \geq 2\), the containment problem of CRPQs in CRPQs with equality relations over \(\Sigma\) is undecidable.

The proof is a consequence of Lemma 2.4 and the undecidability of the emptiness of \(\text{dom}(M)\) for Turing machines \(M\), and the following lemma:

**Lemma 3.2.** Let \(\Sigma\) be an alphabet. For every set \(H = \{H_1, \ldots, H_k\}\) of H-systems over \(\Sigma\), one can effectively construct an alphabet \(\Sigma'\), a CRPQ \(Q_1\) over \(\Sigma'\), and a CRPQ with equality relations \(Q_2\) over \(\Sigma'\) such that \(Q_1 \subseteq Q_2\) if and only if \(L(H) = \Sigma^*\).

**Proof.** Let \(\Sigma = \{a_1, \ldots, a_s\}\) for some \(s \geq 1\). Let \(H\) be a set of \(k\) H-systems \(H = \{H_1, \ldots, H_k\}\) over \(\Sigma\) (with \(k \geq 1\)). We define \(\Sigma' := \Sigma \cup \{\star, \$\}\), where \(\star\) and \$ are distinct letters that do not occur in \(\Sigma\). Next, we define
\[
Q_1 := \text{Ans()} \leftarrow (x, \pi, y), L(\pi),
\]
where \(L := \$\star a_1 \cdots a_s \star \$\star \Sigma^* \star \$, and \(x, y\) are distinct variables. Thus, \(Q_1(G) = \text{true}\) if and only if \(G\) contains a path \(\rho\) with \(\lambda(\rho) \in L\).

The definition of \(Q_2\) is more involved. Informally explained, \(Q_2\) uses the structure provided by \(Q_1\) to implement the union of the languages \(L(H_i)\). We
define $Q_2$ such that, for every db-graph $G$ with $Q_1(G) = \text{true}$, $Q_2(G) = \text{true}$ holds if and only if there is a path $\rho$ in $G$ with $\lambda(\rho) = \mathcal{S}a_1 \cdots a_s \mathcal{S}w \mathcal{S}$, where $w \in L(H_i)$ (i.e., $w \in L(H_i)$ for some $H_i \in \mathcal{H}$).

Note that the paths $\rho$ described by $Q_1$ contain exactly three occurrences of the $\mathcal{S}$ symbol, which can be understood to divide $\rho$ into two parts, where the left part is labeled $\mathcal{S}a_1 \cdots a_s \mathcal{S}$, and the right part is labeled $\mathcal{S}w \mathcal{S}$. Likewise, the query $Q_2$ can be understood as consisting of two parts, which are to be defined in the subqueries $\bigwedge_{1 \leq i \leq k} \phi_i^{\text{sel}}$ and $\bigwedge_{1 \leq i \leq k} \phi_i^{\text{cod}}$, respectively. Our goal is to construct $Q_2$ in such a way that, when matching $Q_2$ to $\rho$, the $\phi_i^{\text{sel}}$ are used to select which H-system $H_i$ is simulated in $Q_2$, while the actual encoding of that H-system is achieved by $\phi_i^{\text{cod}}$ (hence, the superscripts sel and cod). We define $Q_2$ as

$$Q_2 := \text{Ans}() \leftarrow (x_0, c_1^\mathcal{S}, x_1), (x_{k+1}, c_2^\mathcal{S}, x_{k+2}),$$

$$L_\mathcal{S}(c_1^\mathcal{S}), L_\mathcal{S}(c_2^\mathcal{S}), \bigwedge_{1 \leq i \leq k} \phi_i^{\text{sel}}, \bigwedge_{1 \leq i \leq k} \phi_i^{\text{cod}}$$

where $L_\mathcal{S} = \{\mathcal{S}\}$, and the $\phi_i^{\text{sel}}$ and $\phi_i^{\text{cod}}$ consist of relational and labeling atoms that shall be defined further down. As explained above, the subqueries $\phi_i^{\text{sel}}$ are used to select which H-system is active when matching $Q_2$ to a graph. These queries are defined by

$$\phi_i^{\text{sel}} := (x_i, c_i^\mathcal{S}, y_i, 1), (y_{i,1}, c_{i,1}^a, y_{i,2}), \ldots, (y_{i,s}, c_{i,s}^a, y_{i,s+1}), (y_{i,s+1}, c_{i,2}^{\mathcal{S}}, x_{i+1}),$$

$$L^\mathcal{S}(c_i^\mathcal{S}), L_a(c_{i,1}^a), \ldots, L_a(c_{i,s}^a), L_{\mathcal{S}}(c_{i,2}^{\mathcal{S}}), \text{eq}(c_{i,1}^\mathcal{S}, c_{i,2}^{\mathcal{S}})$$

where $L_a := \{\varepsilon, a\}$ for each $a \in \{\mathcal{S}, a_1, \ldots, a_s\}$.

In order to define each $\phi_i^{\text{cod}}$, we need to consider the respective H-system $H_i$: Let $H_i = (\Sigma, X_i, L_i, \alpha_i)$, where $\alpha_i = \beta_{i,1} \cdots \beta_{i,m_i}$ for some $m_i \geq 1$ and $\beta_{i,1}, \ldots, \beta_{i,m_i} \in (X \cup \Sigma)$. We define the relational part of $\phi_i^{\text{cod}}$ to be

$$(\hat{x}_i, c_i^\mathcal{S}, z_i, 1), (z_{i,1}, d_{i,1}, z_i, 2), \ldots, (z_{i,m_i}, d_{i,m_i}, z_{i,m_i+1}), (z_{i,m_i+1}, c_{i,4}^\mathcal{S}, \hat{x}_{i+1}),$$

where $c_i^\mathcal{S}, c_{i,3}$, and all $d_{i,j}$ are (pairwise distinct) new path variables. We start the construction of the labeling part of $\phi_i^{\text{cod}}$ with the labeling atoms $L^\mathcal{S}(c_i^\mathcal{S}), L^\mathcal{S}(c_{i,1}^\mathcal{S}), L^\mathcal{S}(c_{i,2}^\mathcal{S})$, and $\text{eq}(c_{i,1}^\mathcal{S}, c_{i,2}^\mathcal{S})$. Furthermore, we define a regular language $L_{i,j}$ for every $1 \leq j \leq m_i$ by $L_{i,j} := L_i(\beta_{i,j})$ if $\beta_{i,j} \in X$, and $L_{i,j} := \{\varepsilon, \beta_{i,j}\}$ if $\beta_{i,j} \in \Sigma$. In addition to this, we add a label atom $\text{eq}(c_{i,j}^{\beta_{i,j}}, d_{i,j})$ for every $j$ with $\beta_{i,j} \in \Sigma$. Finally, for every $j$ with $\beta_{i,j} \in X$ such that $\beta_{i,j}$ occurs more than once in $\alpha_i$, we add a relation $\text{eq}(d_{i,j}, d_{i,l})$ for every $l \neq j$ with $\beta_{i,l} = \beta_{i,j}$.

Note that the relation graph $H_{Q_2}$ consists only of a path from $x_0$ to $\hat{x}_{k+1}$, where each node (except $\hat{x}_{k+1}$, the last node) has exactly one successor. Thus, the relation graph is acyclic and has no branches.

We claim that $L(H) = \Sigma^*$ holds if and only if $Q_1 \subseteq Q_2$, which completes the proof of Lemma 3.2.

**Proof:** Assume that $L(H) = \Sigma^*$, and let $G = (V, E)$ be a db-graph over $\Sigma'$ with $Q_1(G) = \text{true}$. By definition of $Q_1$, $G$ contains a path $\rho$ with $\lambda(\rho) = \mathcal{S}a_1 \cdots a_s \mathcal{S}w \mathcal{S}$.
\$\phi_1 \cdot \phi_2 \cdot \phi_3 \cdot \phi_4 \cdot \phi_5 \cdot \phi_6 \$ for some $w \in \Sigma^*$. Let $w = b_1 \cdots b_n$ with $n \geq 0$ and $b_j \in \Sigma$ for $1 \leq j \leq n$. Accordingly, there are nodes $v_0, \ldots, v_{s+n+7} \in V$ such that

\[
\rho = v_0 \$ v_1 \star v_2 a_1 v_3 \ldots v_{s+1} a_s v_{s+2} \star v_{s+3} \$ v_{s+4} \star v_{s+5} b_1 v_{s+6} \cdots v_{s+n+4} b_n v_{s+n+5} \star v_{s+n+6} \$ v_{s+n+7}.
\]

See Figure 1 for a graphic representation of this path. Although this does not matter for our considerations, note that these $v_i$ are not necessarily distinct.

In order to show that $Q_2(G) = \text{true}$, we construct a node mapping $\sigma$ and a path mapping $\mu$ such that $(G, \sigma, \mu) \models Q_2$. We first define

\[
\begin{align*}
\sigma(x_0) & := v_0, & \mu(c^0_1) & := v_0 \$ v_1, \\
\sigma(x_1) & := v_1, & \mu(c^0_2) & := v_{s+3} \$ v_{s+4}, \\
\sigma(x_{k+1}) & := v_{s+3}, & \mu(c^0_{k+1}) & := v_{s+4}, \\
\sigma(x_{k+1}) & := v_{s+4}, & \mu(c^0_{k+2}) & := v_{s+n+7}.
\end{align*}
\]

As $L(H) = \Sigma^*$, there is an $i$ with $1 \leq i \leq k$ such that $w \in L(H_i)$. We now want to map the path described in $\phi_{i}^{rel}$ to the path between $v_1$ and $v_{s+3}$ (for an illustration, see Figure 2). In order to achieve this, we define

\[
\begin{align*}
\sigma(x_i) & := v_1, & \mu(c^1_{i,1}) & := v_1 \star v_2, \\
\sigma(y_{i,1}) & := v_2, & \mu(c^1_{i,2}) & := v_2 a_1 v_3, \\
\vdots & & \vdots & \\
\sigma(y_{i,s+1}) & := v_{s+2}, & \mu(c^1_{i,s+2}) & := v_{s+1} a_s v_{s+2}, \\
\sigma(x_{i+1}) & := v_{s+3}, & \mu(c^1_{i+2}) & := v_{s+2} \star v_{s+3}.
\end{align*}
\]

As all other $\phi_{j}^{rel}$ are not needed, we define

\[
\sigma(x_j) :=
\begin{cases}
  v_1 & \text{if } 1 \leq j < i, \\
  v_{s+3} & \text{if } i < j \leq k,
\end{cases}
\]

and $\sigma(y_{j,i}) := \sigma(x_j)$ for all $j \neq i$, $1 \leq j \leq k$ and $1 \leq l \leq s+1$. Accordingly, for all $\pi_j \in \{c^1_{j,1}, c^1_{j,2}, c^1_{j,s+1}, c^1_{j,s+2}\}$ with $j \neq i$, we define

\[
\mu(\pi_j) :=
\begin{cases}
  v_1 \in v_1 & \text{if } 1 \leq j < i, \\
  v_{s+3} \in v_{s+3} & \text{if } i < j \leq k.
\end{cases}
\]
We can already observe that \((G, \sigma, \mu) \models Q_2\) holds modulo the subquery \(\bigwedge_{1 \leq j \leq k} \phi_{j}^{\text{cod}}\), using the following reasoning: As \(\lambda(\mu(c_j^1)) = \$\) for \(j \in \{1, 2, 3\}\), \(\lambda(\mu(c_j^3)) \in L_\$ = \{$\$\}\) is true, and \(L_\$(c_j^8)\) is satisfied. Furthermore, for every \(j \neq i\) with \(1 \leq j \leq k\), we observe
\[
\lambda(\mu(c_j^*)) = \lambda(\mu(c_{i,j}^1)) = \ldots = \lambda(\mu(c_{j,2}^*)) = \varepsilon.
\]
Due to \(\varepsilon \in L_\star, L_{a_1}, \ldots, L_{a_s}\), each of
\[
L_\star(c_j^1), L_{a_1}(c_j^1), \ldots, L_{a_s}(c_j^1), L_\star(c_j^3), L_\star(c_j^3), L\text{eq}(c_j^3, c_j^3)
\]
is satisfied. Similarly, we observe
\[
\lambda(\mu(c_{i,j}^3)) = a_1 \in L_{a_1},
\]
\[
\vdots
\]
\[
\lambda(\mu(c_i^s)) = a_s \in L_{a_s},
\]
which demonstrates that \(\phi_{j}^{\text{ext}}\) is satisfied as well.

All that remains is to find a proper assignment of the variables in \(\phi_{i}^{\text{cod}}\) that describes the second half of \(\rho\), while all other variables describe only the empty path. A graphic representation of the underlying idea can be found in Figure 3.

Accordingly, we define
\[
\sigma(\hat{x}_j) := \begin{cases} 
  v_{s+4} & \text{if } 1 \leq j < i, \\
  v_{s+n+6} & \text{if } i < j \leq k,
\end{cases}
\]
and, likewise,  

$$\sigma(z_{j,l}) := \begin{cases} v_{s+4} & \text{if } 1 \leq j < i, \\ v_{s+n+6} & \text{if } i < j \leq k, \end{cases}$$

for all $l$ such that $z_{j,l}$ occurs in $Q_2$. Consequently, we define  

$$\mu(c_{j,3}^\bullet) = \mu(c_{j,4}^\bullet) = \mu(d_{j,l}) = \sigma(\hat{x}_j) \in \sigma(\hat{x}_j)$$

for all $1 \leq j \leq k$, $j \neq i$.

We observe that for all $j \neq i$ with $1 \leq j \leq k$, $\phi_j^{\text{cod}}$ is satisfied: First, observe that  

$$\lambda(\mu(c_{j,3}^\bullet)) = \lambda(\mu(c_{j,4}^\bullet)) = \varepsilon$$

holds. As $\lambda(\mu(c_{j,3}^\bullet)) = \varepsilon$, all of  

$$L^\bullet(c_{j,3}^\bullet), L^\bullet(c_{j,4}^\bullet), \text{eq}(c_{j,3}^\bullet, c_{j,3}^\bullet), \text{eq}(c_{j,4}^\bullet, c_{j,4}^\bullet)$$

are satisfied. Furthermore, for all $d_{j,l}$ that occur in $\phi_j^{\text{cod}}$, $\lambda(\mu(d_{j,l})) = \varepsilon$. Therefore, every $L_{j,l}(d_{j,l})$ is satisfied, as $\varepsilon \in L_{j,l}$ holds by Definition 2.3. Moreover, as each of these paths is an empty path, all relations $\text{eq}(d_{j,l}, d_{j,l})$ in $\phi_j^{\text{cod}}$ are satisfied as well, which means that $\phi_j^{\text{cod}}$ is satisfied.

As the last remaining task, we need to complete the definition of $\sigma$ and $\mu$ such that $\phi_i^{\text{cod}}$ is satisfied. In order to examine $H_i$ in detail, assume that $H_i = (\Sigma, X_i, L_i, \alpha_i)$, and let $\alpha_i = \beta_{i,1} \cdots \beta_{i,m_i}$ for some $m_i \geq 0$ with $\beta_{i,j} \in (X_i \cup \Sigma)$ for $1 \leq j \leq m_i$. By definition of $w \in L(H_i)$, there is an $H_i$-compatible morphism $h : (X_i \cup \Sigma)^* \to \Sigma^*$.

As $w = h(\alpha_i)$, there is a natural decomposition of $w$ into factors $w_1 \cdots w_{m_i}$, which are defined by $w_j := h(\beta_j)$ for $1 \leq j \leq m_i$. We take special note of the subpaths of $\rho$ that can be derived from these $w_j$, and define  

$$n_0 := s + 5, \quad \hat{v}_0 := v_{n_0} = v_{s+5},$$

$$n_j := s + 5 + |w_1 \cdots w_j|, \quad \hat{v}_j := v_{n_j} = v_{s+5+|w_1 \cdots w_j|}$$

for each $1 \leq j \leq m_i$. Hence, for each $j$, the subpath of $\rho$ between $\hat{v}_{j-1}$ and $\hat{v}_j$ is labeled with $w_j$. Note that $\hat{v}_{j-1} = \hat{v}_j$ might hold, in particular if $w_j = \varepsilon$. Also note that, by definition, $\hat{v}_{m_i} = v_{s+n+5}$.

Hence, we define  

$$\sigma(\hat{x}_i) := v_{s+4}, \quad \mu(c_{i,3}^\bullet) := v_{s+4} \star v_{s+5},$$

$$\sigma(z_{i,1}) := \hat{v}_0 = v_{s+5}, \quad \mu(c_{i,4}^\bullet) := v_{s+n+5} \star v_{s+n+6},$$

$$\vdots$$

$$\sigma(z_{i,m_i}) := \hat{v}_{m_i-1}, \quad \mu(c_{i,3}^\bullet) := v_{s+n+5} \star v_{s+n+6},$$

$$\sigma(\hat{x}_{i+1}) := v_{s+n+6}.$$
Finally, we define each $\mu(d_{i,j})$ with $1 \leq j \leq m_i$ to correspond to the subpath of
$l$ between $\hat{v}_{j-1}$ and $\hat{v}_j$ that is labeled with $w_j$.

We now prove that $L_{i,j}(d_{i,j})$ is satisfied for every $1 \leq j \leq m_i$. As in
the definition of $L_{i,j}$, we distinguish the following cases:

1. If $\beta_{i,j} \in X_1$, $L_{i,j} = L_i(\beta_{i,j})$. As $w_j = h(\beta_{i,j})$, and due to
$h(\beta_{i,j}) \in L_i(\beta_{i,j})$, $\lambda(\mu(d_{i,j})) \in L_{i,j}$,

2. if $\beta_{i,j} \in \Sigma$, $L_{i,j} = L_{\beta_{i,j}}$. As $w_j = h(\beta_{i,j}) = \beta_{i,j}, \lambda(\mu(d_{i,j})) \in L_{i,j}$ holds.

This also proves that, for every $j$ with $\beta_{i,j} \in \Sigma$, $\lambda(\mu(d_{i,j})) = \beta_{i,j} = \lambda(\mu(c^{\beta_{i,j}}))$.
Hence, these relations $eq(c^{\beta_{i,j}}, d_{i,j})$ are satisfied as well. Finally, for every
$\beta_{i,j} \in X_1$ that occurs more than once in $\alpha_i$, we need to consider the relations
$eq(d_{i,j}, d_{i,l})$ for all $l$, with $l \neq j$ and $\beta_{i,l} = \beta_{i,j}$. As $h$ is a morphism, $\beta_{i,j} = \beta_{i,l}$
implies $h(\beta_{i,j}) = h(\beta_{i,l})$, and thus,
\[
\lambda(\mu(d_{i,j})) = w_j = w_l = \lambda(\mu(d_{i,l})).
\]

Obviously, $eq(d_{i,j}, d_{i,l})$ is satisfied. We now have demonstrated that $(\sigma, \mu, G) =
Q_2$. Hence, $Q_2(G) = \text{true}$, and as $G$ was chosen arbitrarily with $Q_1(G) = \text{true}$,
$Q_1 \subseteq Q_2$ follows.

"⇐": We prove this direction through its contraposition; i.e., we show
that $L(H) \neq \Sigma^*$ implies $Q \not\subseteq Q_2$. Assume there is a $w \in \Sigma^*$ with $w \not\in L(H)$.
Let $w = b_1 \cdots b_n$ for some $n \geq 0$ with $b_i \in \Sigma$ for all $1 \leq i \leq k$. We define
$G := (V, E)$, where $V := \{v_0, \ldots, v_{s+n+6}\}$ (and all elements of $V$ are pairwise
distinct), and
\[
E := \{(v_0, S, v_1), (v_1, \star, v_2), (v_2, a_1, v_3), \ldots, (v_{s+1}, a_s, v_{s+2}), (v_{s+2}, \star, v_{s+3}),
(v_{s+3}, S, v_{s+4}), (v_{s+4}, \star, v_{s+5}), (v_{s+5}, b_1, v_{s+6}), \ldots, (v_{s+n+1}, b_n, v_{s+n+2}),
(v_{s+n+2}, \star, v_{s+n+3}), (v_{s+n+3}, S, v_{s+n+4}), (v_{s+n+4}, \star, v_{s+n+5}), (v_{s+n+5}, S, v_{s+n+6}), (v_{s+n+6}, S, v_{s+n+7})\}.
\]

In other words, $G$ is an acyclic graph that consists solely of a path from $v_0$ to
$v_{s+n+7}$ labeled $S\star a_1 \cdots a_s \star w \star S$. As $w \in \Sigma^*$, $Q_1(G) = \text{true}$ holds. For
convenience, we denote this path by $\rho$.

For the sake of contradiction, assume $Q_1(G) \subseteq Q_2(G)$, which necessarily
implies $Q_2(G) = \text{true}$. Thus, there are assignments $\sigma, \mu$ such that $(\sigma, \mu, G) =
Q_2$. As $\lambda(\rho)$ contains exactly three occurrences of $S$, and as $L_S(c^3)$ occurs in $Q_2$
for $1 \leq i \leq 3$, we know that $\sigma$ and $\mu$ must satisfy the following conditions:

\[
\begin{align*}
\sigma(x_0) &= v_0, & \mu(c_1^3) &= v_0 \; S \; v_1, \\
\sigma(x_1) &= v_1, & \\
\sigma(x_{k+1}) &= v_{s+3}, & \mu(c_3^3) &= v_{s+3} \; S \; v_{s+4}, \\
\sigma(\hat{x}_1) &= v_{s+4}, & \\
\sigma(\hat{x}_{k+1}) &= v_{s+n+6}, & \mu(c_3^3) &= v_{s+n+6} \; S \; v_{s+n+7}, \\
\sigma(\hat{x}_{k+2}) &= v_{s+n+7}.
\end{align*}
\]
As eq$(c_{i,1}^\bullet, c_{i,2}^\bullet)$ needs to be satisfied for all $1 \leq i \leq k$, and as the subpath between $v_1$ and $v_5$ contains exactly two occurrences of $\star$, there must be exactly one $i$ with $\lambda(\mu(c_{i,1}^\bullet)) = \star$ (although this $i$ is not necessarily uniquely defined). We shall see that our assumption allows us to conclude that $w \in L(H_i)$, which leads to the intended contradiction. Due to our previous observations, the following must hold:

\[
\begin{align*}
\sigma(x_i) &= v_1, & \mu(c_{i,1}^\bullet) &= v_1 \star v_2, \\
\sigma(y_{i,1}) &= v_2, & \mu(c_{1,i}^\bullet) &= v_2 a_1 v_3, \\
\vdots & & \vdots \\
\sigma(y_{i,s+1}) &= v_{s+2}, & \mu(c_{s,i}^\bullet) &= v_{s+1} a_s v_{s+2}, \\
\sigma(x_{i+1}) &= v_{s+3}. & \mu(c_{i,2}^\bullet) &= v_{s+2} \star v_{s+3}.
\end{align*}
\]

Now, note that $Q_2$ is acyclic. Therefore, the structure of $G$ permits no other assignments than

\[
\sigma(x_j) = \begin{cases} v_1 & \text{if } 1 \leq j < i, \\ v_5 & \text{if } i < j \leq k, \end{cases}
\]

and $\sigma(y_{j,i}) = \sigma(x_j)$ for all $j \neq i$ and all $1 \leq l \leq s+1$. Accordingly,

\[
\mu(c_{j,1}^\bullet) = \mu(c_{1,j}^\bullet) = \ldots = \mu(c_{s,j}^\bullet) = \mu(c_{i,2}^\bullet) = \sigma(x_j) \in \sigma(x_j)
\]

holds for all these $j$. Thus, only the path variables from $\phi_i^{rel}$ are mapped to a nonempty path. The same phenomenon occurs for the variables of $\phi_i^{cod}$. As $Q_2$ contains relations eq$(c_{i,1}^\bullet, c_{i,2}^\bullet)$ and eq$(c_{i,1}^\bullet, c_{i,3}^\bullet)$, we conclude that

\[
\begin{align*}
\sigma(\hat{x}_i) &= v_{s+4}, & \mu(c_{i,3}^\bullet) &= v_{s+4} \star v_{s+5}, \\
\sigma(z_{i,1}) &= v_{s+5}, \\
\sigma(z_{0,m+1}) &= v_{s+n+5}, & \mu(c_{i,4}^\bullet) &= v_{s+n+5} \star v_{s+n+6}, \\
\sigma(\hat{x}_{i+1}) &= v_{s+n+6}
\end{align*}
\]

holds. Let the $H$-system $H_i$ be defined by $H_i = (\Sigma, X_i, L_i, \alpha_i)$, where $\alpha_i = \beta_i \cdot \beta_i = \beta_i m_i$ for some $m_i \geq 0$. By definition of $Q_2$, we know that $\phi_i^{cod}$ contains the path variables $d_{i,1}, \ldots, d_{i,m_i}$ (in addition to $c_{i,3}^\bullet$ and $c_{i,4}^\bullet$). This implies

\[
\lambda(\mu(d_{i,1})) \lambda(\mu(d_{i,2})) \cdots \lambda(\mu(d_{i,m_i})) = b_1 \cdots b_n.
\]

We define words $w_j := \lambda(\mu(d_{i,j}))$ for $1 \leq j \leq m_i$. In order to prove $w \in L(H_i)$, we show that these words can be used to define an $H_i$-compatible morphism $h$ with $h(\alpha_i) = w$. First, we distinguish two possible cases for every $1 \leq j \leq m_i$:

1. If $\beta_i j \in X_i$, $L_i j = L_i(\beta_i j)$ holds by definition of $Q_2$, which implies $w_j \in L_i(\beta_i j)$.  

14
2. if $\beta_{i,j} \in \Sigma$, $w_j = \beta_{i,j}$ must hold, as $Q_2$ contains label atoms $L_{\beta_{i,j}}(d_{i,j})$ and $\text{eq}(e^{\beta_{i,j}}_{i,j})$, and $\lambda(\mu(e^{\beta_{i,j}}_{i,j})) = \beta_{i,j}$.

Furthermore, for all $j \neq l$ with $\beta_{i,j}, \beta_{i,l} \in X_i$ and $\beta_{i,j} = \beta_{i,l}$, $Q_2$ contains a label atom $\text{eq}(d_{i,j}, d_{i,l})$; hence, $w_j = w_l$ holds. This allows us to define a morphism $h : (X_i \cup \Sigma)^* \rightarrow \Sigma^*$ by $h(\beta_{i,j}) := w_j$ for all $1 \leq j \leq m_i$.

Furthermore, as shown above for the two possible cases, $h$ is $H_i$-compatible. Finally, $h(\alpha_i) = h(\beta_{i,1} \cdots \beta_{i,m_i}) = w$ holds by definition.

Thus, $w \in L(H_i) \subseteq L(H)$, which contradicts our initial assumption. This concludes the if-direction of the proof. \qed

By using standard encoding techniques for representing arbitrary finite alphabets by an alphabet of size 2, the proof of Theorem 3.1 now easily follows from Lemma 2.4, the undecidability of the emptiness of $\text{dom}(M)$ for Turing machines $M$, and Lemma 3.2. By using universal Turing machines instead of arbitrary Turing machines, we also obtain the following strengthening of Theorem 3.1:

**Theorem 3.3.** For every alphabet $\Sigma$ with $|\Sigma| \geq 2$, there are a fixed CRPQ $Q_1$ over $\Sigma$ and a fixed CRPQ with equality relations $Q_2$ over $\Sigma$ such that (i) the containment problem of $Q_1$ in CRPQs with equality relations, and (ii) the containment problem of CRPQs in $Q_2$ are both undecidable. This holds even if all queries are Boolean and acyclic.

**Proof.** The first claim follows from the proof of Theorem 3.1 as $Q_1$ is fixed. In order to prove the second claim, we choose $M$ to be a certain kind of universal Turing machine, and use $Q_1$ to choose the program number of the universal machine we want to simulate.

More precisely, let $\Psi : \mathbb{N} \times \mathbb{N} \rightarrow \mathbb{N}$ be a universal partially recursive function, i.e., for every partially recursive function $\phi : \mathbb{N} \rightarrow \mathbb{N}$, there is an $m \geq 0$ such that $\Psi(m,n) := \Psi(m,n) = \phi(n)$ for every $n \geq 0$. It is an elementary fact of recursion theory that such a function exists (cf. Kozen [13]), and moreover, there is a Turing machine $U$ over some tape alphabet $\Gamma$ such that $\text{dom}(U) = \{a^m b^n \mid \Psi(m,n) \text{ is defined}\}$, where $a, b$ are two distinct letters in the input alphabet of $U$. The machine $U$ might be understood as simulating partial recursive function number $\Psi(m)$ (in the numbering that is defined by $\Psi$) on the input $n$.

We define $\Sigma := \Gamma \cup Q \cup \{\#\} = \{a_1, \ldots, a_s\}$ (for some $s \geq 2$) and $\Sigma' := \Sigma \cup \{\star, \$\}$, and construct $Q_2$ and $H$ from $U$ as in the proof of Lemma 3.2. For every $m \geq 0$, we define a CRPQ $Q_{1,m}$ by $Q_{1,m} := \text{Ans()} \leftarrow (x, \pi, y), L_m(\pi)$,

where $L_m := \$ \star a_1 \cdots a_s \star \$ \# \# \# \# \star \star \# \star \star \star \#, $
and proceeding as in the proof of Lemma 3.2, mutatis mutandis. In other words, \( Q_1 \) does not generate arbitrary sequences, but sequences that start with the encoding of all possible initial sequences of simulations of the function \( \Psi_m \).

Then, \( Q_{1,m} \subseteq Q_2 \) holds if and only if \( \text{dom}(U) \cap \alpha^m b^* \) is empty, which holds if and only if \( \Psi_m(n) \) is undefined on all inputs \( n \). As decidability of this problem would allow to decide the emptiness of the domain of partial-recursive functions (an undecidable problem), the second claim follows. Again, the common encoding techniques can be used to replace the alphabet \( \Sigma' \) with a binary alphabet.

Furthermore, all queries used are Boolean and acyclic by definition.

Applying slight modifications to the proof of Lemma 3.2, we observe the same situation for ECRPQs that use length equality instead of equality relations:

**Theorem 3.4.** For every alphabet \( \Sigma \) with \( |\Sigma| \geq 2 \), there are a fixed CRPQ \( Q_1 \) over \( \Sigma \) and a fixed CRPQ with length equality relations \( Q_2 \) over \( \Sigma \) such that (i) the containment problem of \( Q_1 \) in CRPQs with length equality relations, and (ii) the containment problem of CRPQs in \( Q_2 \), are both undecidable. This holds even if all queries are Boolean and acyclic.

**Proof.** As we shall see, it suffices to replace all occurrences of eq in the queries that are constructed according to the proof of Theorem 3.3 (and the other proofs referenced therein) with el.

Note that, in order to prove Theorem 3.1, we do not need to express all possible unions of H-systems, but only those \( \mathcal{H} \) that are derived from a Turing machine \( \mathcal{M} \) as explained in Lemma 2.4. Furthermore, the construction in Lemma 3.2 uses the eq-predicates in two different contexts: First, on path variables that are associated with languages \( \{a, \varepsilon\} \) for some \( a \in \Sigma \), and second, on path variables that simulate variables \( x \) in H-expressions \( (\Sigma, X, L, \alpha) \) such that \( |\alpha|_x \geq 2 \).

For the first case, we can simply replace eq with el without changing the behavior of the query: Obviously, for all \( w, w' \in \{a, \varepsilon\} \), \( w = w' \) holds if and only if \( |w| = |w'| \).

Regarding the second case, note that almost all H-expressions that are derived from the proof of Lemma 2.4 describe regular languages. The only non-regular languages that are constructed describe cases where \( w \neq w' \) holds for certain words \( w, w' \in \Gamma^* \), and characterizes this relation by \( w \neq w' \) if and only if

1. there exist words \( u, v, v' \in \Gamma^* \) and letters \( c, d \in \Gamma \) with \( c \neq d \), \( w = ucv \), and \( w' = udv' \), or
2. exactly one of \( w, w' \) is the empty word.

The first condition holds if and only if there exist words \( u, u'v, v' \in \Gamma^* \) and letters \( c, d \in \Gamma \) with \( c \neq d \), \( w = ucv \), \( w' = u'dv' \), and \( |u| = |w'| \), which demonstrate that in this case, the replacement of eq with el leads to the same results. □
3.2. Query Equivalence

The query equivalence problem is the problem to decide for two input queries \( Q \) and \( Q' \) whether \( Q \equiv Q' \).

Another question specifically posed in [3] is whether the equivalence problem for CRPQs and ECRPQs is decidable. Using a variant of the proof of Theorem 3.3 we can answer this question negatively:

**Theorem 3.5.** For every alphabet \( \Sigma \) with \( |\Sigma| \geq 2 \), there are a fixed CRPQ \( Q_1 \) over \( \Sigma \) and a fixed ECRPQ \( Q_2 \) over \( \Sigma \) such that (i) the equivalence problem of \( Q_1 \) and ECRPQs, and (ii) the equivalence problem of CRPQs and \( Q_2 \), are both undecidable. This holds even if all queries are Boolean and acyclic.

Theorem 3.5 can be obtained from the proof of Theorem 3.3 by using the following lemma instead of Lemma 3.2:

**Lemma 3.6.** Let \( \Sigma \) be an alphabet. For every regular language \( L \subseteq \Sigma^* \) and every set \( H = \{ H_1, \ldots, H_k \} \) of \( H \)-systems over \( \Sigma \), one can effectively construct a CRPQ \( Q_1 \) and an ECRPQ \( Q_2 \) such that \( Q_1 \equiv Q_2 \) if and only if \( L(H) = L \).

**Proof.** Let \( \Sigma, \Sigma', \) and \( Q_1 \) be defined as in the proof of Lemma 3.2 and let \( L \subseteq \Sigma^* \) be a regular language.

We define \( Q_1 := \text{Ans}(x, \pi, y) \leftarrow (x, \pi, y) \), where \( L' := \$^a_1 \cdots a_s \$^L \$ \) (as \( L \) is regular, \( L' \) is regular as well). In order to define \( Q_2 \), we introduce the regular \( k \)-ary relation xor\((w_1, \ldots, w_k)\), which is defined by

\[
\text{xor} := \{(w_1, \ldots, w_k) \mid \text{there is exactly one } 1 \leq i \leq k \text{ with } w_i \neq \varepsilon\}.
\]

We now obtain \( Q_2 \) by adding xor\((c_{1,1}^*, \ldots, c_{k,1}^*)\) to the query \( Q_2 \) used in the proof of Lemma 3.2. Then \( Q_2(G) = \text{true} \) holds if and only if \( G \) contains a path \( \rho \) with \( \lambda(\rho) \in \$^a_1 \cdots a_s \$^L \$ \).

If query equivalence were decidable, we could use Lemma 3.6 to decide whether \( \text{INVALC}(M) = L \) for every Turing machine \( M \) and every regular language \( L \). As this problem is undecidable, query equivalence must be undecidable. Hence, Theorem 3.5 follows.

4. Expressiveness and Relative Succinctness

4.1. Expressiveness of (E)CRPQs

In this section, we examine the expressive power of CRPQs and ECRPQs. In particular, we give a classes of query functions for which we characterize expressibility in CRPQS, and in ECRPQs over unary alphabets.
We say that a query function \( F \) is \textit{CRPQ-expressible} (or \textit{ECRPQ-expressible}) if there is a CRPQ (or ECRPQ, resp.) \( Q \) such that \( Q(G) = F(G) \) for every \( \Sigma \)-labeled \( db \)-graph \( G \).

For every language \( L \subseteq \Sigma^* \), we define a query function \( F_L \) by

\[
F_L(G) := \{(x, y) \mid G \text{ contains a path } \rho \text{ from } x \text{ to } y \text{ with } \lambda(\rho) \in L\}
\]

for every \( \Sigma \)-labeled \( db \)-graph \( G \). Analogously, we define a Boolean query function \( F^B_L \) by \( F^B_L(G) := \text{true} \) if and only if \( F_L(G) \neq \emptyset \).

The proofs presented in this section will use specific \( db \)-graphs \( G_w \) representing strings \( w \in \Sigma^* \) as follows: If \( w = b_1 \cdots b_{|w|} \) (with all \( b_i \in \Sigma \)), we define the \( db \)-graph \( G_w := (V_w, E_w) \) by \( V_w := \{v_0, \ldots, v_{|w|}\} \) (where all \( v_i \) are distinct nodes), and \( E_w = \{(v_i, b_{i+1}, v_{i+1}) \mid 0 \leq i < |w|\} \). Thus, \( G_w \) consists of a path from \( v_0 \) to \( v_{|w|} \) that is labeled with \( w \).

Clearly, if \( L \subseteq \Sigma^* \) such that \( F_L \) is expressible by an ECRPQ \( Q_L \), then for all words \( w \in \Sigma^* \) we have \( w \in L \) iff \( (v_0, v_{|w|}) \in Q_L(G_w) \).

\textbf{Lemma 4.1.} Let \( \Sigma \) be an alphabet, let \( L \subseteq \Sigma^* \). Then \( F_L \) is CRPQ-expressible if and only if \( L \) is regular.

\textit{Proof.} The if-direction is obvious: If \( L \) is regular, the CRPQ \( Q := \text{Ans}(x, y) \leftarrow (x, \pi, y), L(\pi) \) expresses \( F_L \).

To prove the only if-direction, let \( L \subseteq \Sigma^* \), and assume there exists a CRPQ \( Q_L = \text{Ans}(x, y) \leftarrow \bigwedge_{1 \leq i \leq m} (x_i, \pi_i, y_i), \bigwedge_{1 \leq i \leq m} L_i(\pi_i) \)

with \( Q_L(G) = F_L(G) \) for every \( \Sigma \)-labeled \( db \)-graph \( G \).

We will show that \( L \) is regular by considering the restricted class of \( db \)-graphs \( G_w \) for words \( w \in \Sigma^* \).

Obviously, \( Q_L(G_w) \) contains the pair \( (v_0, v_{|w|}) \) if and only if \( w \in L \). The main idea of the proof is as follows: First, we construct a CRPQ \( Q'_L \) that is of a certain normal form, and satisfies \( Q'_L(G_w) = Q_L(G_w) \) for all \( w \in \Sigma^* \). Then, we show that the existence of \( Q'_L \) allows us to construct an NFA \( M \) with \( L(M) = L \), showing that \( L \) is regular.

In order to construct \( Q'_L \), we define a graph \( H := (V, E) \), where \( V \) is the set of all node variables in \( Q_L \), while \( E \) is the set of all \( (x_i, \pi_i, y_i) \) that occurs in the relational part of \( Q_L \). In other words, we make use of the normal form for CRPQs, and interpret \( H^\text{lab}_{Q_L} \) as being labeled with the languages \( L_i \) instead of the path variables \( \pi_i \).

We now define the relation \( \rightarrow \) on \( V \) by \( z_1 \rightarrow z_2 \) if, for some \( j \), there is an edge \((z_1, L_j, z_2) \in E\), and define \( \rightarrow^* \) as the reflexive transitive closure of \( \rightarrow \). Our goal is to construct \( Q'_L \) by turning \( H \) into a graph that is acyclic, satisfies \( x \rightarrow^* z \rightarrow^* y \) for every node \( z \), has \( x \) as maximum of \( \rightarrow^* \), and has \( y \) as minimum of \( \rightarrow^* \).

We achieve this by executing the following modifications to \( V \) and \( E \) in order:
1. For all \( z \in V \) with \( z \xrightarrow{*} x \), remove \( z \) from \( V \), and replace all occurrences of \( z \) in elements of \( E \) with \( x \).

2. for all \( z \in V \) with \( y \xrightarrow{*} z \), remove \( z \) from \( V \), and replace all occurrences of \( z \) in elements of \( E \) with \( y \).

3. for all \( z_1, z_2 \in V \) with \( z_1 \xrightarrow{*} z_2 \xrightarrow{*} z_1 \), remove \( z_2 \) from \( V \), and replace all occurrences of \( z_2 \) in elements of \( E \) with \( z_1 \). Repeat this step as long as such \( z_1, z_2 \) exist.

4. remove all remaining loops from \( z \), i.e., all \((z, L_i, z)\).

Note that, at any point of the construction, we can interpret \((V,E)\) as a CRPQ by “reversing” the construction; i.e., each edge is interpreted as an atom of the relational part, while each edge label corresponds to an atom in the labeling part that expresses the corresponding regular language.

We now prove that for the CRPQ \( Q'_L \) that is derived according to these removals, \( Q'_L(G_w) = Q_L(G_w) \) holds for all \( w \in \Sigma^* \). First, as \( Q'_L \) is obtained from \( Q_L \) by removing relations, \( Q'_L \supseteq Q_L \) holds by definition. For the other direction, we first make the following basic observations. Assume that \( \sigma, \mu \) are assignments with \((G_w, \sigma, \mu) \models Q_L \), \( \sigma(x) = v_0 \), and \( \sigma(y) = v_{|w|} \) for some \( w \in \Sigma^* \).

As \( v_0 \) is of in-degree 0, we know that \( \sigma(z) = \sigma(x) = v_0 \) must hold for all \( z \) with \( z \xrightarrow{*} x \). Likewise, as \( v_{|w|} \) is of out-degree 0, \( \sigma(z) = \sigma(y) = v_{|w|} \) holds for all \( z \) with \( y \xrightarrow{*} z \). Furthermore, as \( G_w \) is acyclic, \( \sigma(z_1) = \sigma(z_2) \) holds for all \( z_1, z_2 \) with \( z_1 \xrightarrow{*} z_2 \xrightarrow{*} z_1 \). Hence, for all languages \( L_i \) on the edges of \( H_{Q_L}^{\text{lab}} \) that were removed during the construction process of \( Q'_L \), \( z \in L_i \) must hold.

Now assume that \( \sigma', \mu' \) are assignments such that \((G_w', \sigma', \mu') \models Q'_L \), \( \sigma'(x) = v_0 \), and \( \sigma'(y) = v_{|w'|} \) hold for some \( w' \in \Sigma^* \) (in other words, \((v_0, v_{|w'|}) \in Q'_L(G_{w'}) \) holds). In order to prove \((v_0, v_{|w'|}) \in Q_L(G_{w'}) \), we define \( \sigma(z) := \sigma'(z) \) for every node variable \( z \) that occurs in \( Q'_L \) (and, hence, also in \( Q_L \)), and \( \mu(\pi) := \mu'(\pi) \) for every path variable \( \pi \) that occurs in \( Q'_L \) (and, hence, also in \( Q_L \)). For the remaining node variables \( z_1 \in \text{nvar}(Q_L) \) that do not occur in \( Q'_L \), define \( \sigma(z_1) := \sigma(z_2) \), where \( z_2 \) is a variable with \( z_2 \in \text{nvar}(Q_L) \) (such a variable must exist, according to the construction procedure). Finally, as explained above, all remaining path variables can be assigned to the empty path for the appropriate node. Hence, \((v_0, v_{|w'|}) \in Q'_L(G_{|w'|}) \) holds. As \( w' \in \Sigma^* \) was chosen freely, this proves \( Q_L(G_{w'}) = Q'_L(G_{w'}) \) for all \( w' \in \Sigma^* \).

Note that there might still exist some \( z \in V \) such that \( x \xrightarrow{*} z \) or \( z \xrightarrow{*} y \) does not hold. In order to simplify our technical construction further down, for each such \( z \), we add an edge \((x, \Sigma^*, z)\) if \( x \xrightarrow{*} z \) does not hold, and \((z, \Sigma^*, y)\) if \( z \xrightarrow{*} y \) does not hold. Again, this does not change the result of the corresponding query on all graphs \( G_w \).

As a last step in our construction of the NFA \( M \) with \( L(M) = L \), let \( e_1, \ldots, e_k \) be any numbering of the edges in \( E \). For every \( z \in V \), let

\[
\begin{align*}
\text{in}(z) & := \{i \mid e_i \in E, e_i \text{ ends in } z\}, \\
\text{out}(z) & := \{i \mid e_i \in E, e_i \text{ starts in } z\}.
\end{align*}
\]
Furthermore, for every $e_i \in E$, let $M_i = (Q_i, \Sigma, \delta_i, q_{0,i}, F_i)$ be a DFA for the language that labels $e_i$. We now construct an NFA $M = (Q, \Sigma, \delta, q_0, F)$ that imitates the matching of $Q'_L$ to graphs $G_w$ by simulating all $M_i$ in parallel.

In principle, $M$ shall guess nondeterministically how the nodes of $V$ are assigned to nodes of $G_w$, and processes the respective edges that are active at a certain point, simulating all possible paths through $(V, E)$ in parallel. If (and only if) there is an assignment of nodes in $V$ to nodes in $G_w$ such that all edges have been processed correctly and all paths end at $y$ at the same time, $M$ accepts.

We define $Q := (Q_1 \cup \{w, d\}) \times \ldots \times (Q_k \cup \{w, d\})$. At every point of the simulation, each edge is either active (then the respective automaton $M_i$ is in some state from $Q_i$), is waiting to be activated (represented by $w$), or is done (represented by $d$).

Hence, the initial state $q_0$ of $M$ is defined by $q_0 := (q_1, \ldots, q_k)$, where $q_i := q_{0,i}$ for all $i \in \text{out}(x)$, and $q_i := w$ for all $i \notin \text{out}(x)$.

In the same spirit, we define $\delta(q, a)$ for each $q = (q_1, \ldots, q_k) \in Q$ and each $a \in \Sigma$ according to the following rules:

1. If $q_i = d$ for some automaton $M_i$, that automaton stays in $d$.
2. For every $z \in V$, $M$ can nondeterministically decide that $z$ has been reached if the following conditions are met:
   
   (a) $\delta_i(q_i, a) \in F$ for all $i \in \text{in}(z)$ (all ingoing edges are allowed to end), and
   
   (b) $q_j = w$ for all $j \in \text{out}(z)$ (all outgoing edges are ready).

Then, every $M_i$ with $i \in \text{in}(z)$ enters $d$ (the “done state”) instead of $\delta(q_i, a)$, and every $M_j$ with $j \in \text{out}(z)$ enters its initial state $q_{0,j}$.

3. All $M_i$ with $q_i \neq d$ that are not affected by such a change of active edges stay in the state $w$ if $q_i = w$, or advance to the respective successor state $\delta_i(q, a)$ if $q_i \in Q_i$.

The construction already suggests that $L(M) = L$.

We illustrate this by examining the behavior of $Q'(L)$ on all graphs $G_w$, as $(v_0, v_{|w|}) \in Q'_L(G_w)$ holds if and only if $w \in L$.

First, assume $w \in L$. Then there exist assignments $\sigma, \mu$ with $(G_w, \sigma, \mu) \models Q'_L$, $\sigma(x) = v_0$, and $\sigma(\mu) = v_{|w|}$. As there is exactly one path $\rho$ from $v_0$ to $v_{|w|}$, and as $\lambda(\rho) = w$, $M$ is able to process $w$ according to the assignments $\sigma(z)$ for all $z \in \text{nvar}(Q'_L)$. This leads to $w \in L(M)$.

For the opposite direction, assume $w \in L(M)$. The node assignment $\sigma$ can be derived from the non-deterministic guesses of $M$, as every change in active edges corresponds to a node in $G_w$. Then $\mu$ can be assigned accordingly, and $\lambda(\mu(\pi_i))$ holds for all path variables $\pi_i$ in $Q'_L$. Consequently, $(G_w, \sigma, \mu) \models Q'_L$, $\sigma(x) = v_a$, and $\sigma(y) = v_{|w|}$ hold, and as the only possible path from $v_0$ to $v_{|w|}$ is labeled $w$, we conclude $w \in L$ (by $Q'_L(G_w) = Q_L(G_w) = F_L(G_w)$). Hence, $L$ is regular.
The situation is not strictly the same for Boolean queries (e.g., if \( L \) contains every single letter of \( \Sigma \), \( F^B_\Sigma(G) = \text{true} \) holds for all non-empty db-graphs \( G \)); but a similar result can be observed:

**Lemma 4.2.** Let \( \Sigma \) be an alphabet with \( |\Sigma| \geq 2 \), let \( a \in \Sigma \), and let \( L \subseteq (\Sigma \setminus \{a\})^* \). Then \( F^B_{a\Sigma} \) is CRPQ-expressible if and only if \( L \) is regular.

For alphabets \( \Sigma \) of size \( \geq 2 \), ECRPQs can express queries \( F_L \) for non-regular \( L \subseteq \Sigma^* \) which, according to Lemma 4.1, are not CRPQ-expressible. For example, for \( L := \{a^n b^n \mid n \in \mathbb{N}\}, F_L \) is not CRPQ-expressible, but is expressed by the ECRPQ \( \text{Ans}(x,y) \leftarrow (x, \pi_1, z), (z, \pi_2, y), L_1(\pi_1), L_2(\pi_2), \text{el}(\pi_1, \pi_2) \), where \( L_1 := a^* \) and \( L_2 := b^* \). For unary alphabets (i.e., alphabets of size 1), however, we can show the following:

**Lemma 4.3.** Let \( \Sigma \) be a unary alphabet, let \( L \subseteq \Sigma^* \). Then \( F_L \) is ECRPQ-expressible if and only if it is CRPQ-expressible.

Before giving a proof of this lemma, let us note that, in spite of Lemma 4.3, there exist ECRPQ-queries over unary alphabets that are not CRPQ-expressible. For example, consider the ECRPQ

\[
Q := \text{Ans}(x,y) \leftarrow (x, \pi_1, z), (y, \pi_2, z), \text{el}(\pi_1, \pi_2),
\]

selecting all pairs of nodes \((u,v)\) in a db-graph \( G \), for which there exists a node \( w \) such that there are paths from \( u \) to \( w \) and from \( v \) to \( w \) of the same length. It should be not too difficult to see that this query is not CRPQ-expressible.

**Proof (Lemma 4.3).** The if-direction holds by definition, as every CRPQ is an ECRPQ. Before we proceed to the proof of the other direction, we introduce some basic definitions. For every \( k \geq 1 \) and every vector \( a \in \mathbb{N}^k \), define \( a\mathbb{N} := \{ai \mid i \in \mathbb{N}\} \). For all sets \( A, B \subseteq \mathbb{N}^k \), let \( A + B := \{a + b \mid a \in A, b \in B\} \). A set \( A \subseteq \mathbb{N}^k \) is linear if there exist \( a_0, \ldots, a_n \in \mathbb{N}^k \) for some \( n \geq 0 \) such that \( A = a_0 + a_1 \mathbb{N} + \cdots + a_n \mathbb{N} \). A set is semi-linear if it is a finite union of linear sets.

Let \( A = \{a_1, \ldots, a_k\} \) be a (finite) alphabet. The Parikh mapping (for \( A \)) is the function \( \psi : A^* \rightarrow \mathbb{N}^k \) that is defined as \( \psi(w) := (|w|_{a_1}, \ldots, |w|_{a_k}) \) for all \( w \in A^* \). We extend this to the Parikh image of a language by \( \psi(L) := \{\psi(w) \mid w \in L \text{ for all } L \subseteq A^* \} \), and say that a language \( L \) is semi-linear if \( \psi(L) \) is semi-linear.

Let \( A \) be any set, and let \( k \geq 1 \). For every \( a_1, \ldots, a_k \in A^k \), we define functions \( \text{proj}_i(a_1, \ldots, a_k) := a_i \) for all \( 1 \leq i \leq k \). In other words, the function \( \text{proj}_i \) projects an element of \( A^k \) to its \( i \)-th component.

For the only if-direction, let \( \Sigma := \{a\} \), and assume there is a language \( L \subseteq \Sigma^* \) such that \( F_L \) is CRPQ-expressible, but not CRPQ-expressible. Then Lemma 4.1 implies that \( L \) is not a regular language.

Assume that \( Q_L \) is an ECRPQ with \( Q_L(G) = F_L(G) \) for every \( \Sigma \)-labeled db-graph \( G \), and assume (recalling Lemma 2.1) that

\[
Q_L = \text{Ans}(x,y) \leftarrow \bigwedge_{1 \leq i \leq k} (x_i, \pi_i, y_i), R(\pi_1, \ldots, \pi_k),
\]
We interpret the regular relation $R$ as a regular language over the alphabet $\{a, \bot\}^k$. Let $\psi : (\{a, \bot\}^k)^* \to \mathbb{N}$ denote the Parikh mapping for $A := \{a, \bot\}^k$. As $R$ is regular, its Parikh set $\psi(R) \subseteq \mathbb{N}^{2^k}$ is semi-linear (cf. Harrison [11]).

We define the set $R_{\text{len}} \subseteq \mathbb{N}^k$ by

$$R_{\text{len}} := \{(\{w_1, \ldots, w_k\} | (w_1, \ldots, w_k) \in R\}.$$ 

In order to show that $R_m$ is semi-linear, let $b_1, \ldots, b_{2^k}$ be the enumeration of $\{a, \bot\}^k$ that corresponds to $\psi$ (i.e., for every $1 \leq i \leq 2^k$, $b_i \in \{a, \bot\}^k$, $\text{proj}_i(\psi(b_i)) = 1$, and all other positions of $\psi(b_i)$ are 0). We define functions $f_i : \mathbb{N}^{2^k} \rightarrow \mathbb{N}$ with $1 \leq i \leq k$ by

$$f_i(n_1, \ldots, n_{2^k}) := \sum_{j: \text{proj}_j(b_i) = a} n_j,$$

and extend this to a function $f : \mathbb{N}^{2^k} \rightarrow \mathbb{N}^k$ by

$$f(\pi) := (f_1(\pi), \ldots, f_k(\pi))$$

for every $\pi \in \mathbb{N}^{2^k}$. It is easy to see that $R_{\text{len}} = f(\psi(R))$. As $\psi(R)$ is semi-linear, there exist an $m \geq 1$ and linear sets $R_1, \ldots, R_m \subseteq \mathbb{N}$ such that $\psi(R) = \bigcup_{i=1}^m R_i$, which leads to $R_{\text{len}} = \bigcup_{i=1}^m f(R_i)$.

Every $R_i$ is a linear set, hence, for every $1 \leq i \leq m$, there exist an $n \geq 0$ and $c_0, \ldots, c_n \subseteq \mathbb{N}^{2^k}$ with $R_i = c_0 + c_1 \mathbb{N} + \ldots + c_n \mathbb{N}$. Therefore, $f(R_i) = f(c_0) + f(c_1)\mathbb{N} + \ldots + f(c_n)\mathbb{N}$, which demonstrates that $f(R_i)$ is a linear subset of $\mathbb{N}^k$. Hence, $R_{\text{len}}$ is semi-linear.

The next step is the construction of a relation that extends $R_{\text{len}}$ by not only describing the lengths of paths that are obtained from a single path variable, but to paths that are formed by connecting these single paths.

A label sequence (in $Q_L$) is a sequence $i_1, \ldots, i_m$ with $m \geq 1$, and

1. $1 \leq i_j \leq k$ for all $1 \leq j \leq m$ (every $i_j$ corresponds to the path variable $\pi_{i_j}$ in $Q_L$),
2. $i_j \neq i_j'$ if $j \neq j'$,
3. there exist $z_0, \ldots, z_m \in \text{nvar}(Q_L)$ such that $(z_j, \pi_{i_{j+1}}, z_{j+1})$ is an atom in $Q_L$ for every $0 \leq j < m$.

Hence, every label sequence describes an non-empty, acyclic path through the relation graph $H^{\text{lab}}_{Q_L}$; moreover, for every labeling sequence, the corresponding node variables $z_0, \ldots, z_m$ are uniquely defined, as every path variable occurs exactly once in the relational part of $Q_L$.

For every label sequence $p$ with corresponding node variables $z_0, \ldots, z_m$, we define $\text{start}(p) := z_0$, $\text{end}(p) := z_m$, and let $\text{lab}(p) \subseteq \{1, \ldots, k\}$ denote all $i_j$ that occur in $p$.

Let $\mathcal{P} = \{p_1, \ldots, p_l\}$ with $l \geq 1$ denote the set of all label sequences in $Q_L$ (as there is only a finite number of path variables in $Q_L$, and no index $i_j$...
occurs twice in a labeling sequence, \( \mathcal{P} \) is finite by definition). Without loss of
generality, assume that \( \text{start}(p_1) = x \) and \( \text{end}(p_1) = y \) hold; i.e., \( p_1 \) corresponds
to a path from \( x \) to \( y \) in \( H_{Q_{L_{lab}}}^{lab} \).

For each \( p_i \) in \( \mathcal{P} \), we define a function \( \hat{p}_i : \mathbb{N}^k \rightarrow \mathbb{N} \) by
\[
\hat{p}_i(r_1, \ldots, r_k) := \sum_{j \in \text{lab}(p_i)} r_j.
\]
Hence, if \( r \in \psi(R) \) (and, hence, corresponds to the path lengths in an assignment
that satisfies \( Q_L \)), \( \hat{p}_i(r) \) is the length of the path between the start\( (p_i) \) and
end\( (p_i) \) along the edges labeled with \( \pi_j \) for \( j \in \text{lab}(p_i) \).

We combine these functions \( \hat{p}_i \) to a function \( \hat{p} : \mathbb{N}^k \rightarrow \mathbb{N}^l \) by
\[
\hat{p}(\tau) := (\hat{p}_1(\tau), \ldots, \hat{p}_l(\tau))
\]
for all \( \tau \in \mathbb{N}^k \), and define
\[
\hat{p}(R_{\text{len}}) := \{ \hat{p}(\tau) | \tau \in R_{\text{len}} \}.
\]
Using the same approach as for \( R_{\text{len}} \), we can conclude that \( \hat{p}(R_{\text{len}}) \) is semi-linear.

Projecting \( \hat{p}(R_{\text{len}}) \) to its first component does not yield the intended contra-
diction, as \( R \) might permit assignments where the path corresponding to \( p_1 \) is
not labeled with a word from \( L \), as long as there exists a different path between
the same two nodes, but with a correct length. The problem holds for all other
pairs of nodes that are connected non-uniquely. To overcome this problem, we
need to enforce that for every pair of nodes, all paths between these nodes have
the same length.

We now define the equivalence relation \( \equiv \) on \( \mathcal{P} \) by \( p_i \equiv p_j \) if start\( (p_i) = \]
start\( (p_j) \) and end\( (p_i) = \)end\( (p_j) \). For every \( 1 \leq i \leq l \), let
\[
S_i := \{(s_1, \ldots, s_l) \in \mathbb{N}^l | s_j = s_i \text{ for all } j \text{ with } p_i \equiv p_j \},
\]
and define
\[
B := \{(s_1, \ldots, s_l) \in \mathbb{N}^l | s_j \leq s_1 \text{ for all } j \},
\]
\[
T := \hat{p}(R_{\text{len}}) \cap B_m \cap \bigcap_{i=1}^l S_i.
\]
First, note that \( B \) and all \( S_i \) are linear. Due to the closure of the class of semi-
linear sets under intersection (cf. Ginsburg and Spanier [10]), \( T \) is semi-linear.

Intuitively, the sets \( S_i \) enforce that all paths with the share the same exterior
nodes are assigned paths of the same lengths. Furthermore, the set \( B \) ensures
that no path is longer than the path described by \( p_1 \). We are now able to state
the claim that shall allow us to finish the proof:

\textit{Claim:} Let \( T_1 := \{ \text{proj}_1(t) | t \in T \} \). Then \( T_1 = \psi_a(L) \), where \( \psi_a : \{a\}^* \rightarrow \mathbb{N} \)
denotes the Parikh mapping of \( \{a\} \).

As semi-linear sets are closed under projection, this implies that \( \psi(L) \subseteq \mathbb{N} \) is
semi-linear, which implies that \( L \) is regular, which shall yield the contradiction.
In order to prove the claim, we examine the behavior of $Q_L$ on a restricted class of $db$-graphs, an approach that is similar to the proof of Lemma 4.1. For every $n \geq 0$, we define the $db$-graph $G_n := G_w$ with $w = a^n$.

**Proof of $\psi_a(L) \subseteq T_1$:** Assume $a^n \in L$ for some $n \geq 0$. Then $(v_0, v_n) \in Q_L(G_n)$ holds by definition, and there exist assignments $\sigma, \mu$ such that $(G_n, \sigma, \mu) \models Q_L, \sigma(x) = v_0$, and $\sigma(y) = v_n$ hold. We define

$$\tau := (\lambda(\mu(\pi_1)), \ldots, \lambda(\mu(\pi_k))),$$

and observe that $\tau \in R$ holds by definition. Hence, for

$$\tau_{len} := (|\lambda(\mu(\pi_1))|, \ldots, |\lambda(\mu(\pi_k))|),$$

we observe $\tau_{len} \in R_{len}$, and, consequently, $p(\tau_{len}) \in p(R_{len})$. As the path that corresponds to $p_1$ (the path from $v_0$ to $v_n$) is the longest possible path in $G_n$,

$$\text{proj}_1(p(\tau_{len})) \leq \text{proj}_1(p(\tau_{len}))$$

holds for all $1 \leq i \leq l$. This allows us to conclude $p(\tau_{len}) \in B$.

Furthermore, for all $p_i, p_j \in \mathcal{P}$ with $p_i \equiv p_j$, there is exactly one path in $G_n$ between $\sigma(\text{start}(p_i))$ and $\sigma(\text{end}(p_i))$. Hence, the two paths that result from the assignment of paths to their paths variables under $\mu$ are identical, which means that $p(\tau_{len}) \subseteq S_i$ holds for all $1 \leq i \leq l$.

Thus, $p(\tau_{len}) \in T$, and $\psi_a(a^n) = n = \text{proj}_1(p(\tau_{len})) \in T_1$.

**Proof of $\psi_a(L) \supseteq T_1$:** Assume to the contrary that there exists an $n \in T_1$ with $n \notin \psi_a(L)$. By definition, there exist a $\bar{\tau} \in T$ with $n = \text{proj}_1(\bar{\tau})$ and a $\tau_{len} \in R_{len}$ with $\bar{\tau} = p(\tau_{len})$.

We now use $\tau_{len}$ to define assignments $\sigma, \mu$ with $(G_n, \sigma, \mu) \models Q_L, \sigma(x) = v_0$, $\sigma(y) = v_n$ as follows: First, we choose $\sigma(x) := v_0$ and $\sigma(y) := v_n$. We then follow $p_1$ and assign paths and nodes according to the respective path lengths in $\tau_{len}$. We then proceed analogously for all other $p_i \in \mathcal{P}$ with $p_i \equiv p_1$. As $\bar{\tau} \in S_j$ holds for all $1 \leq j \leq l$, this process is well-defined.

In order to assign the remaining variables and paths, we first process all $p_i \in \mathcal{P}$ that start at $x$, but end in variables $z$ such that there is no $p_j \in \mathcal{P}$ with $\text{start}(p_j) = z$ and $\text{end}(p_j) = y$. Again, we assign node variables and path variables accordingly. As $\bar{\tau} \in B$, we know that the resulting paths cannot have a length of more than $n$; hence, these assignments are possible. Analogously, we work backwards from $y$, and process all remaining variables that lead to $y$.

Next, observe that for all label sequences $p_i \in \mathcal{P}$ with $\text{end}(p_i) = x$ or $\text{start}(p_i) = y$, $\text{proj}_1(\bar{\tau}) = 0$ must hold, as otherwise, this label sequence and $p_1$ could be concatenated to form a label sequence $p_j \in \mathcal{P}$ with $\text{proj}_2(\bar{\tau}) > \text{proj}_2(\bar{\tau})$, which would contradict $\bar{\tau} \in B$. Hence, all respective node variables can be assign to $x$ or $y$, and all these paths are assigned the empty path.

In terms of the relation graph $H_{Q_L}^{lab}$, this process yields assignments for all node variables $z \in \text{nvar}(Q)$ that are connected to $x$ (or $y$), and the respective path variables that occur on the edges. Any unassigned variable must occur in a subgraph of $H_{Q_L}^{lab}$ that is disconnected from the subgraph that contains $x$. For
each such subgraph, pick a node of in-degree 0 and treat it like \( x \), or a node of out-degree 0 and treat it like \( y \), again working forwards or backwards. Again, \( \overline{t} \in B \) ensures that such an assignment is possible, and \( \overline{t} \in \bigcap_{i=1}^{l} S_i \) prevents inconsistencies as well as problems with cycles.

As \( \sigma \) and \( \mu \) were derived from \( R_{len} \) (and, hence, \( R \)), \((G_n, \sigma, \mu)\) holds. Hence, \((v_0, v_n) \in Q_L(G_n)\), which contradicts \( Q_L(G_n) = F_L(G_n) \), as \( a^n \not\in L \).

In Section 3.1 of [3], Barceló et al. mention that ECRPQs are able to express queries corresponding to *regular expressions with backreferencing* (or *extended regular expressions*) (cf. Aho [1], Freydenberger [8]). These expressions extend the regular expressions with variable binding and repetition operators; e.g., for every expression \( \alpha \), the extended expression \( (\alpha)\%x \ xx \) generates the language of all \( www \) with \( w \in L(\alpha) \) (\( \alpha \) generates some \( w \in L(\alpha) \), \%x assigns that \( w \) to \( x \), and the subsequent uses of \( x \) repeat this \( w \) – hence, \( xx \) generates \( ww \)).

Let \( L := \{a^n \mid n \geq 4, n \text{ is a composite number}\} \). According to Lemma 4.3, \( F_L \) is not ECRPQ-expressible (as \( L \) is not regular). On the other hand, \( L \) is generated by the extended regular expression \( (a a^+)\%x \ x^+ \) (cf. Câmpeanu et al. [5]). This demonstrates that ECRPQs are not able to express all queries that correspond to extended regular expressions.

4.2. Relative Succinctness

In this section, we first obtain an undecidability result on the CRPQ-expressibility of ECRPQs. From this result, we derive a statement of the relative succinctness of ECPRQs in comparison to CRPQs.

We can adapt Lemma 3.2 to observe the following result on the decidability of expressibility:

**Theorem 4.4.** CRPQ-expressibility for ECRPQs is not co-semi-decidable.

**Proof.** This follows from the proof of Theorem 3.5, a variation of Lemma 4.2 and the observation that \( \text{INVALC}(M) \) is regular if \( \text{dom}(M) \) is finite. Regarding the latter, note that if \( \text{dom}(M) \) is finite, \( \text{INVALC}(M) \) is co-finite; if \( \text{dom}(M) \) is infinite, non-regularity of \( \text{INVALC}(M) \) can be established using standard tools. This allows us to effectively construct an ECRPQ \( Q \) from a Turing machine \( M \) such that \( Q \) is CRPQ-expressible if and only if \( \text{dom}(M) \) is finite.

Finiteness of \( \text{dom}(M) \) is a \( \Sigma^0_2 \)-complete problem in the arithmetical hierarchy (cf. Kozen [13]); hence, CRPQ-expressibility is \( \Sigma^0_2 \)-hard, which means that this problem is neither semi-decidable, nor co-semi-decidable.

Using Theorem 4.4 in conjunction with a technique that is due to Hartmannis [12] and has been widely used in Formal Language Theory (cf. Kutrib [14]), we obtain a result on the relative succinctness of ECRPQs and CRPQs. One of the benefits of that technique is that it applies to a wide range of different reasonable definitions of the size of an ECRPQ.

In order to be as general as possible, we define a *complexity measure* for ECRPQs as a computable function \( c \) from the set of all ECRPQs to \( \mathbb{N} \), such that for every finite alphabet \( \Sigma \), the set of all ECRPQs \( Q \) over \( \Sigma \) (i) can be
effectively enumerated in order of increasing $c(Q)$, and (ii) does not contain infinitely many ECRPQs with the same value $c(Q)$. As the following theorem demonstrates, no matter which complexity measure we choose, the size tradeoff between ECRPQs and CRPQs is not bounded by any recursive function:

**Theorem 4.5.** Let $\Sigma$ be a finite alphabet with $|\Sigma| \geq 2$. For every recursive function $f : \mathbb{N} \to \mathbb{N}$ and every complexity measure $c$, there exists an ECRPQ $Q$ over $\Sigma$ such that $Q$ is CRPQ-expressible, but for every CRPQ $Q'$ with $Q' \equiv Q$, $c(Q') > f(c(Q))$.

**Proof.** Let $\Sigma$ be a finite alphabet with $|\Sigma| \geq 2$, and let $c$ be a complexity measure for ECRPQs. Assume to the contrary that there exists a recursive function $f_c : \mathbb{N} \to \mathbb{N}$ such that, for every CRPQ-expressible ECRPQ $Q$ over $\Sigma$, there is a CRPQ $Q'$ with $Q' \equiv Q$ and $c(Q') \leq f(c(Q))$. We shall now demonstrate that this implies that the set

$$\Delta := \{ Q \mid Q \text{ is an ECRPQ over } \Sigma \text{ that is not CRPQ-expressible} \}$$

is semi-decidable. This, in turn, would imply that CRPQ-expressibility for ECRPQs is co-semi-decidable, and contradict Theorem 4.4.

Under our assumptions, the semi-decision procedure for $\Delta$ can be defined as follows: Given an ECRPQ $Q$, compute $n := f_c(c(Q))$, and let $F_n$ be the set of all CRPQs $Q'$ over $\Sigma$ with $c(Q') \leq n$. As $c$ is a complexity measure, $F_n$ is finite. Furthermore, as we can decide whether an ECRPQ is a CRPQ, we can compute a list of all elements of $F_n$ (as we can effectively enumerate all ECRPQs $Q''$ with $c(Q'') \leq n$).

For every $Q' \in F_n$, we semi-decide $Q \neq Q'$ by searching for a $\Sigma$-labeled $db$-graph $G_{Q'}$ with $Q(G_{Q'}) \neq Q'(G_{Q'})$. If $Q' \neq Q$ holds, such a $G_{Q'}$ can be found in finite time, and if we have found a graph $G_{Q'}$ for every $Q' \in F_n$, we let the procedure return 1.

By our choice of $f_c$ (and, hence, $F_n$), $Q$ is not CRPQ-expressible if and only if $Q \neq Q'$ holds for every $Q' \in F_n$. Hence, this procedure is a semi-decision procedure for $\Delta$, which implies that CRPQ-expressibility for ECRPQs over $\Sigma$ is co-semi-decidable. This contradicts Theorem 4.4.

5. Conclusion
