1 **Abstract**

2

3 **Background:** This study investigated whether pedometer-determined activity varies between  
4 summer and winter in normal-weight and overweight adults.

5 **Methods:** Forty-five normal-weight (58% female, age=39.1±12.4 years, BMI=22.2±2.1 kg/m<sup>2</sup>)  
6 and 51 overweight (49% female, age=42.1±12.5 years, BMI=29.3±4.5 kg/m<sup>2</sup>) participants  
7 completed a within-subject bi-seasonal pedometer study. All participants completed two four-  
8 week monitoring periods; one in the summer and one the following winter. Changes in step  
9 counts across seasons were calculated and compared for the two BMI groups.

10 **Results:** Both BMI groups reported significant summer to winter reductions in step counts,  
11 with the magnitude of change being significantly greater in the normal-weight group (-  
12 1737±2201 versus -781±1673 steps/day, *P*=0.02). Winter step counts did not differ  
13 significantly between the two groups (9250±2845 versus 8974±2709 steps/day, *P*=0.63),  
14 whereas the normal-weight group reported a significantly higher mean daily step count in the  
15 summer (10986±2858 versus 9755±2874 steps/day, *P*=0.04).

16 **Conclusion:** Both normal-weight and overweight individuals experienced a reduction in step  
17 counts between summer and winter, however normal-weight individuals appear more  
18 susceptible to winter decreases in ambulatory activity, with the greatest seasonal change  
19 occurring on Sundays. Effective physical activity policies should be seasonally tailored to  
20 provide opportunities to encourage individuals to be more active during the winter,  
21 particularly on weekends.

22

## 1 Introduction

2 Physical activity levels tend to fluctuate according to season, being characteristically highest  
3 during the summer and lowest during the winter. This seasonal pattern has been well  
4 defined in large scale self-report studies conducted in both the USA<sup>1-4</sup> and UK.<sup>5</sup> Self-report  
5 measures of physical activity can however lack validity in that individuals often exhibit an  
6 inability to accurately assess low intensity activities, such as walking behaviour.<sup>6</sup> Walking is  
7 reportedly the most prevalent form of physical activity in both US<sup>7</sup> and UK adults,<sup>8</sup> yet it is  
8 commonly underestimated through questionnaires.<sup>9-11</sup> By not capturing walking or  
9 ambulatory behaviour adequately, self-report studies may lack the sensitivity needed to  
10 detect actual seasonal physical activity patterns.

11  
12 Pedometers are increasingly being used as a surveillance tool to objectively assess free-  
13 living ambulatory activity as they provide an accurate and reliable measure of walking  
14 behaviour by counting the number of steps taken per day. Limited data currently exists  
15 however to describe seasonal changes in the step counts of free-living adults.<sup>12</sup> Due to the  
16 increasing public health burden of obesity,<sup>13</sup> and other diseases related to physical  
17 inactivity,<sup>14</sup> it is essential to understand activity behaviours of different populations to aid in  
18 the development of appropriate public health initiatives.

19  
20 Differences in pedometer-determined activity levels have been previously reported between  
21 different body mass index (BMI) groups,<sup>15-19</sup> with normal weight individuals (BMI < 25 kg/m<sup>2</sup>)  
22 characteristically reporting higher step counts than their overweight (BMI 25–29.9 kg/m<sup>2</sup>) and  
23 obese (BMI ≥ 30 kg/m<sup>2</sup>)<sup>20</sup> counterparts. In addition, differences in activity patterns over the  
24 different days of the week have been reported between normal weight and overweight  
25 adults.<sup>15,16</sup> It is currently unknown however whether normal weight and overweight  
26 individuals exhibit similar or discrete seasonal activity patterns. A clearer understanding of  
27 activity patterns of normal weight and overweight individuals could potentially identify risky  
28 behaviours that could be targeted in the design of obesity prevention programmes. The aim

1 of the current study therefore was to investigate whether pedometer-determined activity  
2 varies between summer and winter in normal weight and overweight adults living in the UK.

3

#### 4 **Methods**

##### 5 ***Design***

6 A within-subjects repeated-measures design was employed, which consisted of two  
7 methodologically identical data collection periods. The first period of data collection took  
8 place during the summer of 2005 (data collected during this time period have been reported  
9 elsewhere<sup>15</sup>) and the second took place six months later during the winter of 2006. This  
10 paper details the findings from those participants completing both the summer and winter  
11 monitoring frames.

12

##### 13 ***Participants***

14 Participants were recruited during the summer of 2005 from two different counties in the  
15 United Kingdom - Leicestershire ( $n = 70$ ) and Cornwall ( $n = 52$ ) - through advertisements  
16 placed in local media. Male and female adult participants were recruited using a sampling  
17 frame that was developed to achieve an equal spread of individuals across the age range of  
18 18 to 65 years. The sampling frame also ensured that, at the study outset, an equal number  
19 of participants were classified as either normal weight ( $BMI < 25 \text{ kg/m}^2$ ) or overweight ( $BMI \geq$   
20  $25 \text{ kg/m}^2$ ), to reflect the 2001 prevalence of overweight in UK adults.<sup>21</sup>

21

22 Upon completion of the summer monitoring frame participants were asked if they would be  
23 willing to repeat the procedure the following winter. Eight participants indicated that they  
24 would not be available during the designated winter testing period, the remaining 114  
25 participants consented and were re-approached the following autumn via email or telephone.  
26 Five participants did not respond to this invitation, whilst 10 met the winter study exclusion  
27 criteria which encompassed any non-seasonal lifestyle change made since completion of the  
28 summer study which may affect physical activity levels (for example, a change in job ( $n = 2$ ),

1 moving house during the study period (n = 2), moved house resulting in changes to  
2 commuting behaviour (n = 1), divorced and changed leisure time physical activity (n = 1),  
3 sustained an injury which influenced walking behaviour (n = 2), and moved away from the  
4 area (n = 2)). Ninety-nine participants started the winter monitoring period.

5  
6 Participants reported being in good general health and none had any physical illnesses or  
7 disabilities that might affect their normal daily routine. The study received ethical approval  
8 from the Loughborough University Ethical Advisory Committee. Participants were informed  
9 about the purpose of the study, they received written and oral information about the study  
10 protocol and provided written informed consent.

11

### 12 ***Measurements of body weight and composition***

13 At the beginning of the study, height was measured without shoes using a wall-mounted  
14 stadiometer (Seca UK, Model: 206, Birmingham, Warwickshire, UK). Body weight and  
15 percentage body fat were measured using a Tanita Body Composition Analyser (Tanita UK  
16 Ltd, Model: BC-418 MA, Middlesex, UK) that measures body fat using 8-point bio-impedance  
17 analysis. Percent body fat measured using the Tanita BC-418 has been shown to correlate  
18 highly with the reference measure of dual-energy X-ray absorptiometry (DXA).<sup>22</sup> As  
19 impedance fluctuates with the distribution of body fluid, to improve accuracy, participants  
20 were required to urinate before the measurement of percentage body fat was taken. BMI  
21 was calculated as kg/m<sup>2</sup>. Measurements of body weight, BMI and percentage body fat were  
22 taken at the beginning of the summer and winter monitoring frames.

23

### 24 ***Pedometer-determined activity***

25 Participants were issued with the same SW-200 pedometer (New Lifestyles, Inc., Lees  
26 Summit, MO) during both monitoring periods. This pedometer has been shown to accurately  
27 detect steps taken in both free-living conditions<sup>23</sup> and under controlled laboratory conditions  
28 using normal weight,<sup>24-26</sup> overweight and obese<sup>27</sup> individuals. The same protocol was

1 employed during both seasons. Participants were instructed to wear the pedometer  
2 throughout waking hours for a period of four weeks, only removing it when either bathing,  
3 showering or swimming. The appropriate position to wear the pedometer, on the waist band  
4 in-line with the midline of the thigh, was shown to participants at the outset. Pedometer  
5 accuracy was confirmed with each participant upon issue by means of a 20 step test  
6 (acceptance criteria: plus/minus two steps). Each night before going to bed participants  
7 recorded the number of steps displayed in an activity log provided. Participants also recorded  
8 whether they had gone for a walk that day, along with any participation in sports and/or  
9 recreational physical activities. The pedometer was then reset ready for the following day.

10

11 All participants were encouraged not to make any changes to their typical daily routine of  
12 work and leisure activity. Upon finishing each monitoring period participants completed a  
13 brief post-study questionnaire enquiring whether they had suffered from any ill health or  
14 made any changes to their normal routine, diet, or general activity levels during the study  
15 period.

16

### 17 ***Meteorological information associated with each monitoring frame***

18 Seasonal changes in physical activity are thought to be mediated through changes in the  
19 environment, with ambient temperature, daylight hours and precipitation considered most  
20 influential.<sup>2,28</sup> Data summarising the mean, minimum and maximum temperature (°C),  
21 sunshine hours and rainfall volume (mm) were therefore collected retrospectively from the  
22 Met Office that corresponded to the summer 2005 and winter 2006 monitoring periods.

23

### 24 ***Statistical analyses***

25 Statistical analyses were conducted using SPSS for Windows version 16. To ensure the  
26 participants completing both monitoring frames did not differ to those completing the summer  
27 period only, the two groups were compared in terms of mean summer step counts, pre-

1 summer study BMI and gender distribution using independent samples *t*-tests and Chi-  
2 squared statistics.

3

4 Summer and winter mean daily step counts were calculated over each four-week monitoring  
5 frame for the normal weight (BMI <25 kg/m<sup>2</sup>) and overweight (BMI ≥25 kg/m<sup>2</sup>) participants.  
6 To test for an overall effect of season, and for an interaction between seasonal change in  
7 steps and weight status, a two-way mixed ANOVA was conducted with season (summer and  
8 winter mean steps) as the within-subjects factor and weight status as the between subjects  
9 factor (normal weight versus overweight). Mean daily step counts reported by the normal  
10 weight and overweight groups in each season were also compared using an independent *t*-  
11 test and effect sizes of the differences in step counts reported between groups were  
12 calculated.<sup>29</sup> For the normal weight and overweight participants the percent change in step  
13 counts between seasons were calculated by dividing the mean seasonal change in steps  
14 (winter minus summer) by mean daily step counts reported in the summer, multiplied by 100.  
15 For each group mean step counts reported on each specific day of the week were calculated  
16 for each season by averaging the 4 step count values available for each day. Using these  
17 data a repeated-measures ANOVA with Bonferroni corrected post hoc comparisons were  
18 applied to test whether mean step counts differed between days within each season. Mean  
19 step counts reported on each day of the week were compared between seasons (e.g.  
20 summer mean Monday steps versus winter mean Monday steps etc.) using multiple paired  
21 sample *t*-tests, with a Bonferroni correction applied. Day-specific seasonal changes in steps  
22 were also calculated (e.g. winter mean Monday steps minus summer mean Monday steps).  
23 The measurements of body weight, percent body fat and BMI were compared between  
24 seasons using paired-samples *t* tests. Statistical significance was set at  $P < 0.05$ .

25

### 26 ***Follow-up-study***

27 A sub-sample of participants from the main study ( $n = 28$ , normal weight:  $n = 17$ , overweight:  
28  $n = 11$ ) agreed to participate in a follow-up study conducted during the summer of 2006. The

1 aim of this follow-up study was to confirm any seasonal changes observed during the main  
2 study and to establish any possible ordering effects that might have been influenced by  
3 pedometer reactivity. The protocol followed was exactly the same as that outlined for the  
4 previous two monitoring frames, and the same exclusion criteria applied to the winter study  
5 were also applied to this follow-up. All participants included in this sub-study remained  
6 healthy throughout according to post-study questionnaire results. Participants who  
7 completed the follow-up were compared to those who did not take part in this additional study  
8 using independent samples t-tests. Mean daily step counts taken by this sub-sample of  
9 normal weight and overweight participants, during each of the three monitoring frames, were  
10 compared using a repeated measures ANOVA, with Bonferroni corrected comparisons  
11 applied in the event of a significant seasonal effect.

12

## 13 **Results**

### 14 ***Meteorological information***

15 Meteorological data recorded by the Met Office for Cornwall and Leicestershire, along with  
16 the national average for England, during the monitoring periods (summer 2005, winter 2006,  
17 summer 2006) are shown in Table 1. Due to the relatively small size of the country, large  
18 differences in climate between regions do not exist. Large climate-related differences in  
19 activity between our participants recruited from Cornwall and Leicestershire were therefore  
20 not anticipated and no significant differences in mean daily step counts were observed  
21 between participants from each location in either season (Summer: Leicestershire sample =  
22  $10837 \pm 3119$  steps/day versus Cornwall sample =  $10056 \pm 2966$  steps/day,  $P=0.213$ ; Winter:  
23 Leicestershire sample =  $9729 \pm 2685$  steps/day versus Cornwall sample =  $8709 \pm 3027$   
24 steps/day,  $P=0.09$ ).

25

26

*Insert Table 1 about here*

27

28

## 1 **Participants**

2 Of the 99 participants who started the winter monitoring period, 3 were lost at follow-up.  
3 Ninety-six participants (78.6% of those used in the analysis of the summer monitoring period)  
4 therefore completed both the summer and winter monitoring frames. Participants who  
5 completed only the summer section of the study did not differ significantly to those who  
6 completed both the winter and summer sections with respect to; summer mean daily step  
7 count, pre-summer study BMI or gender proportion ( $P>0.05$ , data not shown).

8

9 Forty-five normal weight and 51 overweight participants completed the two monitoring  
10 periods. Demographic characteristics of the normal weight and overweight groups are  
11 shown in Table 2, along with a summary of the seasonal activity data reported by participants  
12 in each group. Participants provided 5324 person-days of pedometer data, of a possible  
13 5376 (99% compliance). There were no significant differences between the normal weight  
14 and overweight participants in terms of the number of days the pedometer was worn during  
15 each season (Summer: normal weight =  $27.6\pm 0.7$  days versus overweight =  $27.8\pm 0.6$  days,  
16  $P=0.10$ ; Winter: normal weight =  $27.7\pm 0.7$  days versus overweight =  $27.7\pm 0.7$  days,  $P=0.66$ ).  
17 Furthermore, the number of days in which the pedometer was worn did not differ significantly  
18 between the two seasons for either participant group ( $P>0.05$ ). All participants remained in  
19 good health during the summer and winter monitoring periods and no changes to daily  
20 routine or lifestyle were reported.

21

22

*Insert Table 2 about here*

23

24 The normal weight participants exhibited no significant changes in body weight and BMI  
25 between the summer and winter monitoring periods, however a significant increase in  
26 percentage body fat was observed in the winter in this group ( $t=2.4$ ,  $P<0.02$ ) (Table 2). In  
27 comparison, significant increases in body weight, BMI and percentage body fat were

1 observed between the summer and winter monitoring periods in the overweight group (all  
2  $P<0.05$ ) (Table 2).

3

#### 4 ***Differences in summer and winter step counts***

5 Results of the two-way mixed ANOVA revealed a significant overall effect of season, with  
6 both groups exhibiting significant reductions in mean step counts between summer and  
7 winter ( $F=40.3$ ,  $P<0.001$ ). Normal weight participants showed a consistent summer to winter  
8 reduction in mean step counts on every day of the week (Table 3), with this group reporting  
9 an overall mean winter reduction in ambulatory activity of 1736 steps/day (effect size = 0.62).  
10 The overweight group reported an overall mean winter reduction in ambulatory activity of 781  
11 steps/day (effect size = 0.43). A significant interaction effect of BMI group was observed,  
12 with the normal weight group exhibiting a significantly larger winter reduction in mean daily  
13 step counts in comparison with the overweight group ( $F=5.8$ ,  $P=0.02$ ) (Figure 1). The normal  
14 weight participants exhibited on average a 15.4% reduction in step counts in the winter in  
15 comparison with a 6.9% reduction in steps seen in the overweight group ( $t=2.49$ ,  $P=0.02$ ,  
16 effect size = 0.25). During the summer monitoring period, the normal weight participants  
17 reported a significantly higher mean daily step count than the overweight group ( $t=2.1$ ,  
18  $P=0.04$ , effect size = 0.21), however no statistically significant differences in mean step  
19 counts were observed between the two BMI groups during the winter monitoring period  
20 ( $t=0.49$ ,  $P>0.05$ ) (Figure 1).

21

22

*Insert Figure 1 about here*

23

#### 24 ***Day-of-the-week variations in step counts***

25 No significant variations in step counts were observed in the normal weight group over the  
26 different days of the week during the summer monitoring period ( $F=2.1$ ,  $P>0.05$ ) (Table 3). A  
27 significant day-of-the-week effect was observed in this group however during the winter  
28 monitoring frame ( $F=4.4$ ,  $P<0.001$ ), with step counts reported on a Sunday being significantly

1 lower than those reported on all other days (all  $P < 0.002$ ). In the overweight group a  
2 significant day-of-the-week effect was observed during both seasons (summer:  $F = 4.2$ ,  
3  $P < 0.001$ ; winter:  $F = 3.8$ ,  $P < 0.001$ ), with step counts reported on a Sunday being significantly  
4 lower than those reported on all other days of the week during summer and winter (all  
5  $P < 0.002$ ) (Table 3).

6

7

*Insert Table 3 about here*

8

### 9 **Follow-up study**

10 Participants who completed the follow-up study (normal weight:  $n = 17$ , overweight:  $n = 11$ )  
11 did not differ significantly from the remainder of the sample with regards to summer 2005 and  
12 winter 2006 mean daily step counts (all  $P > 0.05$ , data not shown). Significant differences in  
13 mean daily step counts were observed across the three seasons in the normal weight  
14 participants (summer 2005 =  $11213 \pm 2399$  steps/day, winter 2006 =  $9554 \pm 2952$  steps/day,  
15 summer 2006 =  $11085 \pm 3222$  steps/day,  $F = 9.98$ ,  $P < 0.001$ ), with post hoc analyses revealing  
16 that step counts reported in the winter of 2006 were significantly lower than those reported  
17 during both summers (2005 and 2006). No significant overall effect of season was observed  
18 in the follow-up sample of overweight participants (summer 2005 =  $9245 \pm 2271$  steps/day,  
19 winter 2006 =  $8260 \pm 2289$  steps/day, summer 2006 =  $8701 \pm 2052$  steps/day,  $F = 1.92$ ,  
20  $P = 0.172$ ),

21

### 22 **Discussion**

23 The aim of this study was to determine whether pedometer-determined activity varies  
24 between summer and winter in normal weight and overweight adults. Reductions in  
25 ambulatory activity were observed in both BMI groups in the winter monitoring period, and  
26 this was accompanied by significant increases in percentage body fat measured in the winter  
27 relative to the summer in both groups. The magnitude of seasonal change in activity was  
28 greater in the normal weight participants studied suggesting that normal weight individuals

1 are more prone to seasonal fluctuations in ambulatory activity. The changes in ambulatory  
2 activity observed in the current study reflect changes in ambient temperature and sunshine  
3 hours measured in the UK at the time of each monitoring frame, supporting previous  
4 evidence suggesting that seasonal changes in physical activity are mediated through  
5 changes in the environment,<sup>2,28</sup> particularly the weather.<sup>30</sup>

6

7 The observed changes in ambulatory activity are consistent with seasonal changes in activity  
8 reported in questionnaire-based surveys of physical activity,<sup>1-5</sup> accelerometer-determined  
9 physical activity<sup>31</sup> and pedometer-determined activity, whereby a sample of adults living in  
10 the US reported winter reductions in step counts.<sup>12</sup> This paper is the first of its kind however  
11 to distinguish between normal weight and overweight adults, living in the UK, when  
12 describing seasonal patterns in ambulatory activity.

13

14 The findings from the follow-up sample of normal weight participants studied in the summer  
15 of 2006 showed that this group of participants increased their activity levels, relative to the  
16 winter monitoring period, the following summer. No significant differences in step counts  
17 recorded between the two summer monitoring periods (2005 and 2006) were observed in this  
18 group demonstrating that these normal weight individuals re-attained their increased activity  
19 levels the following summer. Whilst this follow-up sample did not differ significantly from the  
20 rest of the sample in terms of summer 2005 and winter 2006 step counts, it is not possible to  
21 determine whether the same pattern was observed in the normal weight participants who did  
22 not complete the follow-up study. Indeed, seasonal changes in activity could have potential  
23 health consequences if such individuals do not re-attain their activity levels the following  
24 summer. Whilst a winter reduction in mean daily step counts was observed, in comparison  
25 with the two summer monitoring periods, in the follow-up sample of overweight participants  
26 the magnitude of seasonal change was not statistically significant supporting the observation  
27 made from the whole sample of overweight participants that overweight individuals appear to  
28 be less susceptible to seasonal changes in activity. Encouraging overweight individuals to

1 make the most of the summer weather by increasing their activity levels to the level observed  
2 among the normal weight participants during this season could be an effective starting point  
3 for strategies aimed at reducing the prevalence of obesity in the UK.

4  
5 Whilst the normal weight participants showed a consistent summer to winter reduction in  
6 mean step counts on every day of the week, the greatest seasonal change in steps appeared  
7 to occur on Sundays for this group. The mean reduction in steps between the summer and  
8 winter monitoring period on Sunday was 2503 steps/day. It was evident that the normal  
9 weight group maintained their activity levels throughout the week during the summer, as no  
10 day-of-the-week effects occurred during this monitoring frame. However, during the winter  
11 period step counts were significantly lower for this group on a Sunday in comparison with all  
12 other days. As the majority of participants who completed this study worked Monday through  
13 to Friday, it is likely that the step counts reported on Saturdays and Sundays are reflective of  
14 general lifestyle and leisure-time activities. Public health messages and the provision of  
15 suitable in-door facilities that encourage activity on a Sunday during the winter months could  
16 potentially reduce the magnitude of seasonal changes in activity observed in the normal  
17 weight participants surveyed. The development of such facilities and public health messages  
18 may also be effective in encouraging overweight individuals to increase their activity levels on  
19 a Sunday, given the decreases in activity that were also seen in this group on this particular  
20 day of the week across both seasons.

21  
22 In addition to highlighting differences in seasonal activity between normal weight and  
23 overweight adults, the findings of the current study also have methodological implications in  
24 that data collection restricted to one season may either overestimate or underestimate year  
25 round habitual ambulatory activity, particularly in normal weight adults. For example, in the  
26 summer monitoring period 60% of the normal weight group reported mean daily step counts  
27 above the recommended 10,000 steps/day, this figure fell to 36% in the winter monitoring  
28 period. The proportion of overweight participants achieving at least 10,000 steps/day during

1 the summer and winter monitoring periods were 43% and 35% respectively. Similar to the  
2 findings of Tudor-Locke et al,<sup>12</sup> we observe that in order to obtain a non-biased reflection of  
3 general day-to-day step count levels, pedometer studies should either be conducted  
4 throughout different time points over the year, or restricted to spring or fall to avoid the  
5 summer peaks and winter troughs in activity reported herein.

6

7 A limitation of the current study is the fact that only seasonal summaries of meteorological  
8 data were available, and thus it was not possible to statistically assess any relationships  
9 between step counts and the climate. Future studies should overcome this by recording daily  
10 weather conditions concurrently with step count data. Another limitation is the fact that data  
11 were collected from a self-selected sample. The current findings should therefore be  
12 confirmed in, preferably a random sample of adults, recruited from a number of regions  
13 throughout the UK. Furthermore, the size of the follow-up sample assessed in the summer of  
14 2006 was relatively small in comparison to the sample size of the main study which  
15 potentially led to a lack of statistical power to detect differences between the seasons in the  
16 overweight group. A further limitation, common to pedometers, is the fact that they do not  
17 measure physical activity using only upper body movements, neither do they measure  
18 activity associated with cycling or swimming. Results from this study should therefore be  
19 interpreted in context with the study aim; to assess seasonal variation in ambulatory activity.

20

21 Despite these limitations, this study was the first of its kind to describe seasonal patterns in  
22 ambulatory activity, measured objectively, in a sample of normal weight and overweight  
23 adults living in the UK. Given daily step counts measured in normal weight, overweight and  
24 obese adults living in the UK,<sup>16</sup> and in other European countries<sup>32,33</sup> tend to be higher by  
25 approximately 3000 to 4000 steps/day, than those observed in US adults,<sup>18,19,34,35</sup> it is  
26 important to understand habitual activity levels and patterns in different populations to aid in  
27 the formulation of appropriate, population-specific, public health messages. Furthermore,  
28 given the diverse global climate, and as seasonal changes in physical activity are thought to

1 be partly mediated through changes in the weather,<sup>2,28,30</sup> it is likely that seasonal patterns in  
2 ambulatory activity may vary between countries, and more regionally specific studies are  
3 necessary if we are to understand global patterns in activity. A strength of our study is the  
4 four-week monitoring frame applied in both seasons which increases the likelihood that we  
5 have captured participants habitual activity and any reactivity effects, a potential validity  
6 threat to short-term pedometer studies<sup>36,37</sup> have been minimised.

7

8 In conclusion, step counts in the sample of UK adults surveyed decreased significantly in the  
9 winter compared to the summer, with the normal weight participants appearing more  
10 susceptible to winter decreases in ambulatory activity. Public health messages that  
11 encourage overweight adults to take advantage of the warmer weather during the summer  
12 months by increasing their activity levels during this season could be an effective starting  
13 point for strategies aimed at reducing the prevalence of obesity in the UK. Effective physical  
14 activity policies should be seasonally tailored to provide opportunities to encourage  
15 individuals to be more active during the winter. For example, encouraging physical activity,  
16 through indoor activities, particularly on a Sunday could potentially reduce the magnitude of  
17 seasonal changes seen in normal weight adults, and may also help to encourage overweight  
18 adults to increase their activity levels on this particularly in-active day of the week.

## Seasonal differences in step counts

- 1 Table 1
- 2 A summary of the mean temperature, sunshine hours and rainfall volume recorded in
- 3 Cornwall and Leicestershire, along with the national average for England, by the Met Office
- 4 during the Summer of 2005, Winter 2006 and Summer 2006.

Location		Temperature (°C)			Sunshine hours	Rainfall volume (mm)
		Mean	Min	Max		
Cornwall	Summer 2005	15.6	11.4	19.9	619.9	210.2
	Winter 2006	4.4	1.6	7.2	180.0	236.8
	Summer 2006 (follow-up)	16.5	12.0	21.1	688.2	155.9
Leicestershire	Summer 2005	15.9	11.1	20.7	577.4	169.8
	Winter 2006	3.8	1.1	6.6	173.0	119.8
	Summer 2006 (follow-up)	17.2	12.0	22.4	654.1	152.8
England	Summer 2005	15.9	11.2	20.5	583.3	174.8
	Winter 2006	4.0	1.2	6.8	177.9	144.1
	Summer 2006 (follow-up)	17.0	12.0	22.0	676.4	154.2

5

6

- 1 Table 2
- 2 Demographic characteristics of the normal weight and overweight participants along with
- 3 each groups mean daily step counts, minutes reported walking and minutes reported
- 4 engaged in sports and/or recreational physical activities during the summer 2005 and winter
- 5 2006 monitoring frames. Data are mean (SD) values unless otherwise stated.

## Seasonal differences in step counts

	Normal weight participants (n = 45)				Overweight participants (n = 51)			
	Summer	Winter	Seasonal change	Within group differences (p value)	Summer	Winter	Seasonal change	Within group differences (p value)
	Mean (SD)	Mean (SD)			Mean (SD)	Mean (SD)		
Age (years)	39.1 (12.4)				42.1 (12.5)			
Height (cm)	168.8 (10.5)				169.5 (9.7)			
Percent female	58%				49%			
Percent from Cornwall	40%				51%			
Body weight (kg)	63.3 (9.0)	63.3 (9.2)	0	0.988	83.8 (11.5)	84.7 (11.8)	0.9	0.013
BMI (kg/m <sup>2</sup> )	22.2 (2.1)	22.2 (2.2)	0	0.984	29.3 (4.6)	29.6 (4.6)	0.3	0.015
Percent body fat	20.5 (9.0)	21.5 (8.6)	1.0	0.020	30.2 (9.5)	31.8 (9.7)	1.6	<0.001
Overall seasonal mean steps/day	10986 (2858)	9250 (2845)	-1736	<0.001	9755 (2874)	8974 (2709)	-781	0.002
Medium (IQR) minutes reported walking/day*	18.7 (7.3, 30.8)	8.5 (1.9, 20.1)	-10.2	0.001	12.1 (3.2, 22.0)	4.4 (0, 13.9)	-7.7	0.03
Medium (IQR) minutes reported in other activities/day*	7.7 (0.5, 21.3)	6.1 (0, 25.2)	-1.6	0.688	4.3 (0, 17.1)	1.1 (0, 17.7)	-3.2	0.442

1 \* due to skewed data, the median and inter-quartile ranges are reported for the self-reported  
 2 time spent walking, and time engaged in other recreational physical activities data. Within  
 3 group seasonal differences in time spent walking and time engaged in other activities were

- 1 compared using the Wilcoxon Signed Ranks Test. Paired t-tests were used for the remaining
- 2 within-group comparisons reported in the table.
- 3

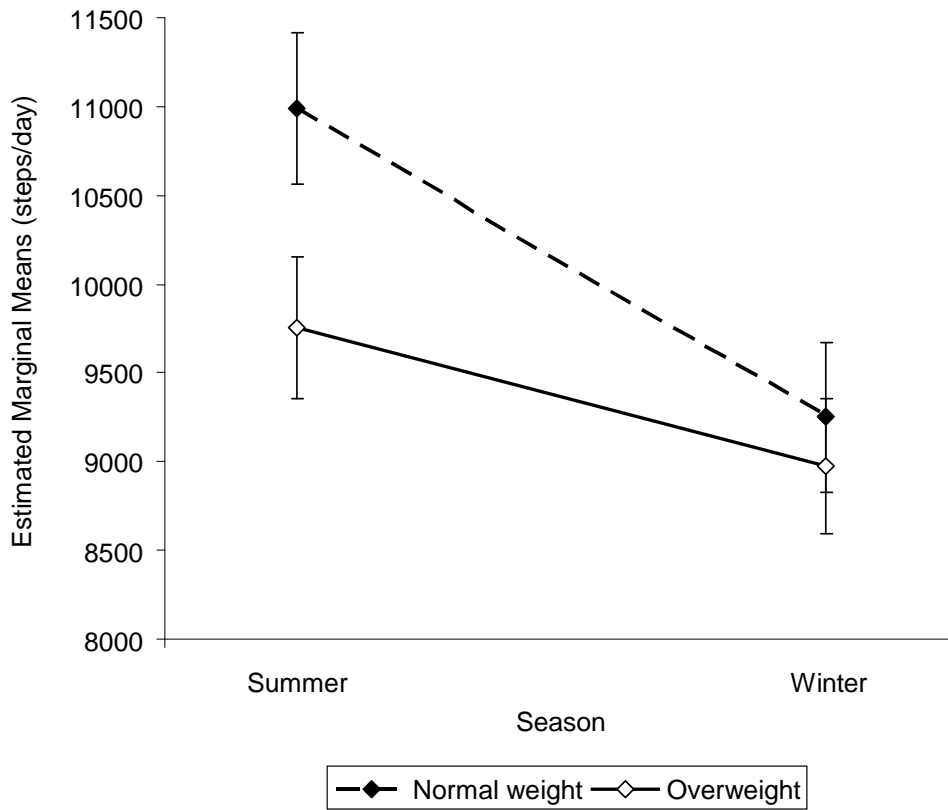

## Seasonal differences in step counts

- 1 Table 3
- 2 Mean (SD) daily step counts reported on each day of the week by the normal weight and
- 3 overweight participants during the summer 2005 and winter 2006 monitoring frames.

	Normal weight participants (n = 45)				Overweight participants (n = 51)			
	Summer	Winter	Seasonal	Within	Summer	Winter	Seasonal	Within
	Mean (SD)	Mean (SD)	change	group	Mean (SD)	Mean (SD)	change	group
			differences				differences	
				(p value)				(p value)
Monday	10524 (3412)	9006 (3249)	-1518	<0.001	10223 (3305)	9055 (3202)	-1168	0.001
Tuesday	11176 (3481)	9666 (3465)	-1510	<0.001	9850 (3323)	9457 (3593)	-393	0.236
Wednesday	11026 (3547)	9716 (3705)	-1310	0.007	10165 (3509)	9201 (3209)	-964	0.011
Thursday	10929 (3555)	9138 (3443)	-1791	<0.001	9732 (3845)	9222 (3674)	-510	0.111
Friday	11177 (3197)	9495 (3029)	-1682	<0.001	9913 (3430)	9232 (3352)	-681	0.114
Saturday	11733 (3714)	9901 (4447)	-1832	0.004	10089 (4329)	9014 (3702)	-1075	0.063
Sunday	10327 (3526)	7824 (3143)	-2503	<0.001	8312 (3162)	7637 (3017)	-675	0.184
Within								
group/season	p >0.05	p <0.001*			p <0.001*	p <0.001*		
differences								

- 4
- 5 \* within group differences, mean daily step counts reported on a Sunday were significantly
- 6 lower than those reported on all other days of the week by the normal weight group during
- 7 the winter, and by the overweight group during both summer and winter.
- 8
